We will suppose, however, that our evergreens have been ordered from a reliable firm and have just come to hand nicely packed, in a truckload if a quantity has been obtained, packed singly or in baskets or bundles if the order is smaller. They may, of course, have been delivered by road; if they have come by rail, however, have them carted away at the earliest possible moment. Open the sacking or other material which surrounds the roots of one or two typical specimens to see what conditions the roots are in as regards moisture. Supposing the roots not to be over-dry and that planting can be finished within a few days, lay them all in trenches not too far from the positions they are to occupy, with the sacking in place. If the roots are on the dry side, but not dusty dry, fill the trench so made with water before returning the soil around the roots. If, however, the balls are dried right through, it will be necessary to dip the trees (preferably tops as well) in a pond or trough. In such case, to prevent, as far as may be, the ball falling to pieces, it is usually well to secure the sacking, or whatever it is that holds the ball, yet more tightly about the roots with some strong tarred twine. When, after a few hours' soaking—overnight is not too long—the plants are removed from the water, lay them in a semi-recumbent position in a shallow trench and cover with soil. Planting in such case had better be postponed for three or four days to enable the ball of earth around the roots again to become homogenous before the sacking is finally removed and they are placed in their permanent quarters.

Where the roots on arrival are in good order but planting cannot all be done for some considerable time, unpack the roots of all which cannot

RHODODENDRON SUTCHUENENSE WITH RATHER BELL-SHAPED ROSY-LILAC FLOWERS.

of allowing such structures to remain empty and fall into disrepair, or removing them, as was done with the large conservatory at Chatsworth, many such houses might be utilised as shelters for the early-flowering Rhododendrons, and would be very suitable for the purpose. These Rhododendrons could be planted out permanently in beds and borders, or cultivated in large pots and tubs. The latter course would permit of their being taken outside in summer. The expense of upkeep without artificial heat would be comparatively small. The protection from spring frosts and cold winds afforded the flowers and young growths by the structures themselves would be sufficient under ordinary circumstances.

Some of the most important Rhododendrons for large structures include the many forms or varieties and hybrids of R. arboreum, together with RR. barbatum, Thomsoni, Falconeri, argenteum (which by some authorities includes R. grande), ciliatum, sutchuenense, lutescens, Nobleanum, dauricum and var. mucronulatum, campylocarpum, praecox, Griffithianum, moupinense, Schlippenbachii, Luscombei and Fargesii.

Attention may also be drawn to the value of the free-growing, early-flowering Rhododendrons for the heated greenhouse from Christmas onwards. Comparatively young flowering plants of most of the kinds mentioned can be accommodated in 10in. and 12in. pots at the outside. A. O.

The ground is still warm enough for conifers and other evergreen trees and shrubs to move well; the fall of the leaf is upon us, so that deciduous stuff may be lifted without danger; the bulk of herbaceous plants may now be put in place; there is still time to plant a great variety of spring-flowering bulbs; and last, but by no means least, one may still lift and relay turf with the consciousness that it will be re-established by winter. When considerable alterations are under way, it is an immense convenience to be able to carry through the work from start to finish without a break. It is proposed in the following notes to touch briefly upon the different classes of planting and to point out some of the stumbling blocks which often lead to failure.

As regards the Coniferae and other evergreen trees and shrubs, much of the ill-success which each year attends such planting is due to the purchase of "cheap," unsuitable stock in the first instance. Exceptionally low-priced stock can only come to be offered in one of four ways. In the first place, it may be of foreign, probably Dutch origin; Dutch stock usually grows, but their methods of "working" are not ours, and their plants are too often debarked by the stock upon which they are "worked" from attaining the characteristics which properly mark the species. Secondly, "cheap," showy stock may be readily produced by failing to transplant, and by letting the top

be planted in the ground within four or five days and set them in an upright position and not too thick on a piece of vacant ground, providing stake and string or other convenient means of support to prevent rocking during the period of their stay. It is surprising the amount of new roots such shrubs will make at this season in a fortnight's sojourn in the reserve ground. Care must, naturally, be taken not to damage these new roots when lifting and replanting these temporarily planted shrubs.

Take out a hole amply large enough for the specimen which is to go into it, and if there is a hard ball, take great care to see that it is nowhere left hollow. It is well to take out the hole rather deeper than would be necessary to bring the surface of the ball to the proper level and to set the ball upon a raised mound in the centre to lift it to the proper height. If the soil is then added little by little and worked with the feet under the ball and tramped and rammed firm as the work proceeds, there should be little doubt as to the success of the transplantation. Staking of shrubs which have a ball is not practicable. Three guy-wires to pegs driven into the ground at a little distance will, however, afford the necessary support. The stem should be carefully padded where these wires are attached, and the wires themselves should be detached next summer and, if necessary, be replaced. They are a necessary evil, but many shrubs are each year beheaded by wires or even string encircling their stems, and which had been forgotten.

One other important point arises in the planting of evergreens, namely, the treatment of shrubs the roots of which were lifted in a ball but of which the ball has become fissured. There is no doubt that in such case the ball is best entirely removed, since no method of filling the crevices satisfactorily with soil presents itself. Dip the broken ball into a vessel of water just about deep enough completely to cover the ball. Fix in an upright position and allow to soak awhile. Then with the hands (under water) gently liberate the soil from the roots. On no account lift the tree from the water until the soil is removed or many of the brittle roots will come away with lumps of water-logged soil. Plant at once and stake firmly.

Deciduous trees are much easier to manage. It is seldom that they present any real difficulty. As they have no ball, they may be soaked if at all on the dry side without difficulty, and they may be staked instead of "guyed" into place. Drive in the stake and secure the tree before filling in the hole. This ensures that the roots are not damaged when the stake is driven in. It is usually recommended to place the stake to windward of the tree. This is a good rule in the case of orchard planting, but in ornamental planting one wishes, naturally, to place the stake as far as possible in the background. Wrap the tree with two or three thicknesses of material where the tie is to come, and take care that the stake cannot chafe the tree anywhere else in its length.

If land to be planted with trees and shrubs is at present under turf, bastard-trench it and lay the turves, face downward of course and chopped sufficiently to be quite solid, in the bottom. Only in exceptional instances is it necessary to provide manure for newly planted shrubs.

Rose trees are never any the worse for having their wood plumped up before planting. It is a good plan, therefore, to leave them to soak, roots and tops, for an hour before planting them or laying them in. The importance of carefully laying in all classes of hard-wooded plants which cannot be planted forthwith cannot be over-estimated. A thoroughly enriched soil is desirable for Roses, and good turfy loam, half-rotted dung and crushed bones should all play their part in enriching the ground. Drainage, too, is most important. Plant Roses deeply so that the junction of scion and stock may be buried.

Practically all that need be said about fruit trees has already been set forth when writing of

deciduous trees and shrubs. Do not specially enrich the soil, for thrifty growth preceeds fruitfulness. Above all, and this applies to all classes of trees and shrubs with equal force, do not allow anyone, under the pretext of "making the tree firm," to lift the tree up and down when the soil has been partially filled in, thus drawing the roots up together. It will be noted that very little has been said about spreading out the roots, which with some people is a fetish. Arrange the roots of all deciduous trees and shrubs (and of such evergreens as come without a ball) just as they appear to have been in the nursery lines. Do not on any account attempt to twist the roots to make a better "balance."

BULBS AND HOW TO USE THEM

THE season has come when Japanese Lily bulbs should be with us in quantity, but we are still in some doubt as to what effect the disastrous earthquake and its *sequelæ* will have upon deliveries. Upon the uses of Lilies alone a long article might be written, but the matter has recently been dealt

the early-flowering Gladioli—G. Colvillei and the rest—which, if planted too soon, are apt to get their growths damaged by spring frosts.

The early-flowering Tulips are rather formal in effect, though less so than first or second size Hyacinths, and they look best when bedded quite formally in beds on the terraces or in other purely

CROCUS VERNUS NATURALISED AT WARLEY PLACE.

with at some length in these columns, and this opportunity is being taken for a final note upon the use and arrangement of spring-flowering bulbs.

There is still ample time to plant Tulips with every hope that they will give of their best and, as far as the May-flowering sections are concerned, if planted in suitable soil, leave a good stock for use in following years. Narcissi and, in particular, soft-bulbed kinds, such as Fritillaria, Scilla (the nutans section) and Erythronium should, ere this, have been recommitted to the earth, yet if the bulbs handle firmly and look sound, they should give excellent results next spring and be useful for permanent planting, though a certain shortage of flower in 1925 may indicate the abuse to which they were subjected this autumn. The end of this month or November is soon enough to plant

formal parts of the garden. Planted about 8ins. apart each way, they may well be underplanted with some dwarf-growing spring-bedding plant. Tulip Rose Griselin or Rose Luisante and Forget-me-not Sutton's Royal Blue form a deservedly popular combination, but Tulip Artus (or Proserpine) and white Arabis, and Tulip Chrysolora with white Polyanthes are equally good. Primrose Queen Tulip is also very effective above a thick planting of Royal Blue Forget-me-not, and even better associated with the purple old-fashioned Bedding Viola Bluebell.

The May-flowering Tulips are not nearly so stiff as the earlier-flowering ones, so that it is little wonder that gardeners lament their inability to naturalise them in turf, but, as this is impracticable, we can at least use them in comparatively

small, natural-looking clumps, where the beauty of the individual blossoms may be better admired than in the too usual straight rows and formal beds. A clump of six bulbs is almost large enough, but if we use six bulbs of each variety, we shall soon get an effect of monotony which will take from the natural grace of the flowers almost as much as if they were formally bedded. Flower-lovers with an eye for colour grouping have long realised the importance of a certain repetition of the main colour *motif* in a planting, just as a painter feels the need for it in his picture. In the garden this is not infrequently obtained by planting a relatively large group and a small one a little distance off to continue the "feeling." Two birds may, therefore, be killed with one stone if we plant a few of our more striking Tulips in appreciably larger groups, with one or two subsidiary groups of smaller size near at hand—so placed, in fact, that without any undue stretching of the imagination, a friend unacquainted with the habits of Tulips might think the original clump had seeded and reproduced itself at a little distance.

For this style of planting the clumps should not be circular, not even all of a shape, but, as in all good planting, the groupings should on an average be proportioned to the shape of the border, using narrow drifts for a long, relatively narrow border and more compact masses for a short "stubby" one. In no case should the lie of a group cross the general line of the planting. A group which is deeper from front to back than from left to right is wholly wrong in a border.

When we come to the bulbs which we are wont to naturalise, the Narcissus, Bluebell, Snakeshead, Dog's Tooth Violet, Camassia and such-like, the matter might seem simpler, but, in fact, the arrangement of groups in so-called natural planting is anything but easy. Were it otherwise we should see really satisfactory wild garden planting more frequently than is, in fact, the case.

A certain woodenness of the grouping, often noticed, can be readily overcome by scattering the bulbs from the hand and planting them where they fall, but this is really only a minor fault. The general grouping is usually unsatisfactory; indeed, there is often no grouping to criticise, the planting being continuous over a large area. This is perhaps allowable with the Bluebell in woodland planting, where the play of light and shade gives a natural and pleasing effect of grouping; it is far from beautiful where plantings of the Daffodil or Snakeshead are concerned. It may be urged that often a corner of a field is found entirely covered with a Lent Lily, Narcissus Pseudonarcissus, but beyond the attraction of the sheer mass of colour there is little real beauty in such a wild planting. It is towards the edges of such a station that we may sometimes find colonies so arranged as to form a really effective grouping. We are, after all, under no obligation to imitate the first natural arrangement we find; there is much grouping in nature that is not beautiful. It is our task, as reasoning beings, to select and imitate the most beautiful, rejecting everything that is less worthy.

Consider every such planting from several viewpoints as a painter's composition, study the fall of the lines so that the eye is led to the features of greatest interest rather than distracted by a bewildering mass of lines, some of which lead quite out of the picture. Plant to form the pictures the eye has visualised and the effect cannot be other than pleasing. Do not attempt in such planting to have too many varieties in flower at once, and plant in drifts rather than in clumps. These points, of course, follow from what has gone before, but perhaps it is as well to set them down. Do not be afraid to plant two varieties which flower at different seasons in association. This should ensure two displays where otherwise only one would be possible.

Early Daffodils and Snakesheads (*Fritillaria Meleagris*) or early "Duffs" and Poet's Narcissus come to mind in this connexion, while, if the turf be short and sweet, *Scilla sibirica* and Winter Aconites may be planted for a still earlier blossoming. Bold masses of *Crocus vernus*, too, may be grouped among the Narcissus, but not intermixed with them, for their flowering times overlap.

Neither Crocus nor Narcissus, nor any other bulb, should be planted in the level close-shaven lawn. Not only do the blossoms lose much in appearance in such a position, but the effect upon the grass, of the period of waiting while the bulb foliage withers, is very detrimental to the lawn. If the garden is small and there is no space for rough grass, preferably contoured, let the naturalising be restricted to a few drifts of Narcissus or Bluebells beneath a little grove of Nut bushes. The beauty of an effect depends rather upon its proportioning than upon its size.

THE CORSICAN HEATH

THE Ericas come to the garden lover with so many and varied charms that selection becomes a matter of real difficulty. Perhaps one's peat patch is rather confined, and therefore one has to be specially critical before admitting a new-comer. One will not be wrong in planting *Erica stricta*, the Corsican Heather, for there is no season in the year when it does not look attractive, though most of all when the ends of the shoots are decked with their pale red flowers in autumn. It is notable among Heaths as a very erect grower and, though of compact habit, capable in course of time of attaining a stature of 3 ft., or even considerably more. In addition to the flowering season, the plants are extremely decorative during summer when covered by the young foliage.

THE BEAUTIFUL NARCISSUS PALLIDUS PRÆCOX UNDER NUT BUSHES.

THE GREAT AUTUMN SHOW

The Great Autumn Show took place at Heriott and Sons' Garden, Heriott Park, Hill, on October 12 and 13, and must be accounted a great success despite the unfavourable weather. Even on the evening when the climatic conditions were at a bad as they well could be, there was a large number of people about the exhibits. The group of plants that could be suggested for a great autumn display is a better lighted list than, alas! so is not to be practical politics. The most noteworthy exhibits will be found listed below under their different sections.

TREES AND SHRUBS

If we except Roses and Clematises, which are in classes by themselves, it was certainly autumn tints that made the greatest appeal among the various collections of hardy trees and shrubs. The most vivid of this colouring was seen in the sprays of *Berberis Thunbergii splendens*, *Quercus pedunculata*, *Euonymus alatus* and *Parrotia persica* which Messrs. J. Cheal and Sons associated with the green of a few conifers and the soft yellow of *Koeleria paniculata*.

But the most brilliant colour of all was in the plants of *Berberis Sargentiana* which Mr. G. Kenthe had in his group. This was almost a startling blood red hue. *Euonymus campanulatus*, smaller in size, was also of rich colour, while several of the Japanese Maples in various

varieties seemed to be more highly coloured than most. The hanging bunches of berries on some bushes of *Viburnum theophrasti* were, in their shining scarlet colour, very decorative.

While such gorgeous hues "took the eye" and the space held it, it was realised that the deep green or evergreen species had quite as much to show. The satisfying restfulness of the ample foliage of such *Rhododendrons* as *Talcenti*, *extremum maximum* and *Hedgson* was evident in one large collection.

The massed green in the large group which Messrs. Hilber and Sons arranged was, when the light was fading and just before the electric lighting was switched on, almost black in its intensity. They had a valuable collection of young specimens of the newest Chinese Spruces and Silver Firs, so very interesting to the tree lover. A collection which was also of interest was set up by Messrs. A. Charlton and Sons, and among other valuable shrubs they had good specimens of *Kriobotrya japonica*.

Not far away from the large circular group of Michaelmas Daisies which Mr. H. J. Jones arranged so well Messrs. R. and G. Cuthbert had a collection of trees and shrubs which included *Acer Negundo variegata*, *Hollies*, dwarf conifers and *Ceanothus Gloire de Plantières*.

The dwarf conifers which are so valuable for planting in the rock garden were to be seen in perfection in the exhibits of Mr. G. G. Whitelegg and Mr. Clarence Elliott, who shewed many Junipers of contrasting habits. There were

spreading little bushes which would mask a large boulder and give overhead shade to plants which require it, and there also were tiny little examples of the silvery green upright Irish Juniper, *Minutaria* Spruces of compact, almost congested, habit and often of perfect columnar form were also freely shown.

In a fascinating general group Messrs. Wallace and Co. had several young plants of *Cytisus prostratus* which, in their erect habit and grey-green foliage, were very valuable. They had various other shrubs, and margined the whole group with *Frica vagans* varieties and *Daboecia polifolia* interspersed with beautiful masses of *Colchicums*. They also shewed groups of various Dahlias, Gladioli and other flowers in generous quantities.

Clematises were grouped in quantity by Messrs. Lockman and Sons and Messrs. L. K. Russell, Limited, who, as was remarked by a veteran visitor, have entirely discarded the old method of training this shrub on to large balloon shapes and now shew them in a more natural and pleasing manner. From the gallery, under artificial light, the dozen or so plants of the white-flowered *Marie Boisselot* in Messrs. Russell's collection were especially effective, and illustrated the value of white flowers for the evening garden. *Princess of Wales*, silvery blue, and *Lady Betty Balfour*, shades of royal purple, provided a pretty colour scheme in this one flower. *Jackmanni rubra*, *Ville de Lyon* and *Gipsy Queen* were other beautiful varieties.

THE NEW BUDDLEIA 'MOONLIGHT' WITH CREAMY BELL FLOWERS.

A VERY ORNAMENTAL PRIVET, LIGUSTRUM QUIHOUT.

ROSES

Those who, on entering, turned to the right might well have thought that it was an Autumn Rose Show, for there were masses of most glorious Roses stretching along as far as the eye could reach. Mr. George Prince had a most beautiful collection, arranged with considerable skill. Columbia, Lady Plymouth, Covent Garden, Golden Emblem and Etoile de Hollande are the names of only a few of the excellent varieties he set up so well.

In an entirely distinct fashion Mr. E. J. Hicks shewed his Roses. He had full-sized arches of most beautiful Ophelia, Melody and Mine. Butterfly. There were also tall stands, like so many columns, of Golden Ophelia, Columbia, Hugh Dickson and Climbing Lady Hillingdon, as well as other sorts.

A well arranged collection was contributed by Messrs. B. K. Cant and Sons, who had Emma Wright of splendid colouring. Mrs. E. Powell, Modesty, Padre and Mrs. W. Christie Miller were also noteworthy. The Rev. J. H. Pemberton had, mostly, varieties of his own raising, and chief among them were Moonlight, Nur Mahal, Aurora and Mermaid.

Last year's new varieties, Lady Inchquin and Betty Uprichard, were set out on arches by Messrs. Alex. Dickson and Co., who also shewed Lady Pirrie, Sunstar, Betty Hulton (a good yellow colour) and the new Shot Silk, which had a fascinating sheen of peach pink. Their new pink Hybrid Tea was to be seen in a collection by Messrs. F. Cant and Co.

In most collections the garden variety Emma Wright was to be seen and of lovely colouring, but in none was it better than as shewn by Messrs. Chaplin Brothers. Golden Emblem, Mrs. Hy. Morse, Innocence, Red Letter Day and the deliciously fragrant Walter C. Clarke were also of excellent quality. Mr. John Mattock included Martha Drew, Souv. de Claudius Pernet and Margaret Dickson Hamill; while Messrs. Waterer, Sons and Crisp had such valuable sorts as Los Angeles, Lady Pirrie, K. of K., Ophelia and General McArthur.

It was very late in the season for Sweet Peas, but Messrs. Dobbie and Co. were able to set up

PART OF MESSRS. BUNYARD'S FINE EXHIBIT OF HARDY FRUITS.

goodly vases of Picture, Royal Scot, Royal Purple, Hawmark Pink, Constance Hinton and other sterling varieties.

FRUITS AND VEGETABLES

There were some excellent exhibits of fruits and two magnificent exhibits of vegetables. The last two were deservedly awarded the coveted "Gold," and the Hon. Vicary Gibbs, in addition to the gold medal, received the Coronation Cup for the most meritorious group in the Show. Messrs. George Bunyard and Co. received a gold medal for a splendid exhibit of fruit. The famous Maidstone firm, as usual, shewed some remarkably fine specimens, which were tastefully displayed in fancy baskets. Here were to be seen among the Apples St. Everard, Mabbott's Pearmain, Wealthy, Rev. W. Wilks, Red Victoria, Cox's Orange Pippin, Rival, Ellison's Orange and Old

Royal Russet. Among the Pears were Catillac, Doyenne du Comice and Pitmaston Duchess. The fruits were beautifully coloured and of the highest quality. The Barham Nurseries, Limited, were awarded a large silver cup for a very representative collection of Apples and Pears. We noted such excellent Apples as Cox's Pomona, Blenheim Orange, Cellini Pippin, Wealthy and King of the Pippins; while Pears Durrondan and Beurré Diel were well to the fore.

Messrs. Daniels Brothers, Limited, secured a small silver cup for a fine lot of fruit which had been gathered from two and three year old bushes and pyramids. Cox's Orange Pippin was shewn in good condition, as were such notable sorts as Blenheim Orange, Charles Ross, Worcester Pearmain and Norfolk Beauty. Pears Conference, Glou Morceau and Pitmaston Duchess were very prominent on this stand. Messrs. Daniels also shewed their now famous September Black Currant. A large and excellent exhibit was staged by the Orpington Nurseries, Limited. Here were to be seen such well known Apples as Cellini Pippin, James Grieve, Ben's Red (superbly coloured), King of the Pippins and Hoary Morning. Among the Pears, Conference was to the fore. Besides the Apples and Pears, the Orpington Nurseries shewed Nottingham Medlar and Orpington Prolific Gage.

Messrs. E. Spooner and Sons shewed some fine specimens of Apples. Those that "caught the eye" were Cellini Pippin, Cox's Orange Pippin, Wealthy, Lane's Prince Albert and Hounslow Wonder.

The Horticultural College, Swanley, sent up an excellent collection of Apples and Pears. Mr. E. R. Watts of Colchester shewed, besides Apples and Pears, several bunches of Grapes which had been grown in a cold house. Here also were to be seen Peaches, Medlars and Mulberries. From the Midlands came a praiseworthy and tastefully arranged collection of Apples and Pears. This fruit had been grown at the Studley Horticultural and Agricultural College for Women.

A magnificent collection of fruit trees in pots was exhibited by Mr. J. C. Allgrove, who had splendidly trained trees of Peach Merlm, Plums Coe's Golden Drop and President, Apples S. J. Wright and Ontario. It is not often that one sees the Parsley-leaved Blackberry grown in a pot, but Mr. Allgrove had a fine specimen which was laden with luscious fruits. By introducing into this group bold pillars of Rosa Moyessi and

THE SPLENDID VEGETABLE EXHIBIT FROM ALDENHAM HOUSE.

R. Farquhar Mr. Allgrove made an exceptionally decorative and attractive exhibit. The Roses were laden with hips. Two other exhibits of outstanding interest were those of Messrs. T. Rivers and Son and Messrs. John Waterer, Sons and Crisp. Messrs. Rivers had some excellent pot trees of Grapes Gros Maroc, Gros Colmar, Black Alicante and Lady Hall. Here, too, were Apples Cox's Orange, of good size and excellent quality, Peasgood's Nonsuch and James Grieve. The exhibit of Messrs. John Waterer, Sons and Crisp contained trained trees of their new Apple John Waterer. The fruits, which are obviously "culinary," are of immense size. Excellent specimens of Apples Allington Pippin, Ribston

exceptional interest to many visitors were the Custard Marrows.

Messrs. Herbert Chapman, Limited, shewed several novelties. Tomato Blood Orange, a yellow fruit with a curious infiltration of red which makes the name a good one, is said to be of excellent flavour. Their new Capsicum Rother-side Mammoth evoked much interest. Vegetable Marrow Rother-side Orange is of proved value, and is becoming well known as the best-flavoured variety. Their new seedling climbing stringless French Bean No. 5 should also prove of value.

An extensive exhibit of Potatoes was staged by Messrs. Dobbie and Co. Here we saw their new early maincrop Lochiel. The tubers are of

MESSRS. SUTTON'S NEW POTATO BEN CRUACHEN.

and Rev. W. Wilks and Pear Doyenne du Comice were also shewn in a really noteworthy collection.

A truly remarkable exhibit of vegetables was staged by Messrs. Sutton and Sons. In all there were 225 dishes. Never before has such an extensive exhibit been staged by the famous Reading firm or anyone else. It struck the writer, when standing before this exhibit, it would be such a lengthy business to set down all the kinds included that it would be much easier to jot down the names of any not to be found in this display; yet, with all this catholicity, every specimen was of the highest quality. Here were Parsnips and Carrots of immense size, Celery, Leeks, Tomatoes (red and yellow), Runner Beans, Onions, Egg Plants, Chilies, Radishes, Brussels Sprouts and so on. A novelty in the centre of this exhibit was Potato Ben Cruachen, which was awarded Lord Derby's medal this year by the Ormskirk Potato Society for the best new immune Potato grown in competition at the Potato Festive Stakes at Ormskirk. One sometimes wonders where Messrs. Sutton keep all their trophies!

The other vegetable exhibit came from the Hon. Vicary Gibbs. Mr. Edwin Beckett, that past master of vegetable growing, is to be congratulated on placing before the horticultural world such a wonderful array of vegetables. Like the exhibit of Messrs. Sutton and Sons, it contained everything in the vegetable line. Of

good size, of a roundish stone shape and the skin smooth. We have not tried this variety, so cannot speak of its culinary value. However, one need have no fears of its being a "dud." Whatever comes from Edinburgh in the Potato line is good; our friend Mr. William Cuthbertson sees to that. Here, too, were such well known varieties as Immune Ashleaf, Majestic, Rhoderick Dhu, May Queen and Arran Rose.

In the competitive classes, both for fruit and vegetables, competition was not particularly keen in many classes. However, the specimens generally were of splendid quality. An excellent exhibit of vegetables was displayed by the Rev. J. Davies of Worcester, and he was deservedly awarded the Sutton Cup.

CHRYSANTHEMUMS

Chrysanthemums were not so extensively displayed as might have been expected, especially when it is remembered how flowers of the border varieties predominate in the florists' windows and in the baskets of the itinerant vendors. Messrs. Keith Luxford and Co. had a great many of these hardy varieties, mostly in the form of decorative sprays. Rose Chatillon, Verona, Polly and Harry Thorpe are excellent examples. So also are Bronze Normandy, Shrapnel, Dolores, Hesperus, Framfield Early White, September Glory and Roude Blanches, which Mr. William Randall staged so well.

HARDY BORDER FLOWERS

Viewing the Show from the galleries, Michaelmas Daisies seemed to dominate all the other hardy flowers. This impression was due quite as much to the method of displaying the flowers as to the fact that there were countless numbers of Sturges about the hall. The great central group of Mr. H. J. Jones was a very imposing affair. His series of tall columns made up of flowering branches was not at all a natural method, but inasmuch as it displayed to the full a great many varieties, it was very successful. The Ericoides section were well shewn as growing plants. The pillars of Rachael Ballard, Wonder of Colwall, Beauty of Ronsdorf and the new Snowdrift displayed excellent varieties.

A quite distinct method was adopted by Messrs. Dickson and Robinson, whose aim was to arrange the plants as naturally as possible, and this was a particularly happy inspiration which was also of great value to those who contemplated purchasing new varieties, for they could see at a glance the average as well as relative height of any of the many varieties. Walkden's Pink, Robinson V.C. and Calliope were very attractive, though Seedling No. 192, a deep rose pink, was the very best of all their plants, if not the best variety in the Show. It is a distinct advance towards the ideal really pink-flowered variety which raisers are striving for. The erect, free-flowering spike is very graceful and reminiscent of William Bowman, but an immense improvement on that popular variety. Until quite recently pink colouring in Michaelmas Daisies was confined to the variety just named and to Lil Fardel, but now there are plenty to choose from and of much better colouring. Pink Perfection—an unfortunate name, by the way, as the variety will certainly be superseded by a Super Pink Perfection—Autumn Glow, as shewn by Messrs. Dickson and Robinson. Rachael Ballard of deeper shade, as well as Walkden's Pink above named are quite good representatives. The largest-flowered variety in the hall was King George, a dwarf free-flowering mauve variety, also in the collection of Messrs. Dickson and Robinson.

Mr. E. Ballard, who has raised so many splendid varieties, set up his Michaelmas Daisies much after the style of a West Country hedge, which often spreads out at the base. Prominence was given to Grey Lady, a very pale lavender slightly rose flushed at the tips of the florets, which was delightful. Bee's Blush is of slighter brighter tone, while Countess is still deeper in shade of colour. His semi-double variety Little Boy Blue is of such a dark blue that it appeared almost black in the "dim religious light" of the hall.

The Gladioli season is nearing its close, but Messrs. Lowe and Gibson and Messrs. Kelway and Son are still able to put up presentable collections, and other growers associated Gladioli with general border flowers. Most of those staged by Messrs. Lowe and Gibson were unnamed seedling *Primulinus* hybrids of considerable beauty, but they also shewed large-flowered varieties, and of these White Glory and Titanic, rosy cardinal, were particularly good. Queen Mary, a shapely white flower which has crimson blotches on the lower segments, Golden Measure and d'Orsay, orange scarlet heavily splashed on white ground, were very charming in Kelway's collection.

A very good collection was also displayed by Messrs. R. H. Bath, Limited, whose Gladioli included Red Emperor, Pink Perfection, Halley, Le Maréchal Foch and Brillant. A number of Delphiniums with Michaelmas Daisies and other herbaceous flowers were shewn by Messrs. Blackmore and Langdon in conjunction with their plants.

of double-flowered tuberous Begonias which bore such immense blooms of beautiful colouring. John Mercer (orange yellow), Lady Cory (pale orange) and Hilda Langdon (soft pink) among the Begonias were especially handsome.

Excellent Delphiniums were also contributed by Mr. T. Carlile, who had a very large group of first-rate seasonable flowers. His herbaceous Phlox were also of much more than average merit: the trusses were exceptionally large for so late in the season, and the colours were very clean and good. He also included many valuable varieties of *Lupinus polyphyllus* and *Helenium*. *Clematis heracleaefolia* Columbine, one of the most effective herbaceous kinds we have seen, with quantities of mid-blue tubular flowers, was also included. Lupins, shown as "Regal Lupins" were massed by Messrs. Harkness and Sons in a large group. Named Pentstemons were the prominent feature of a collection by Mr. John Forbes.

The Astilbes (Spiraeas), which are useful for growing either in the general border or, preferably, in moist places, were shown by Messrs. Bakers, Limited. *Astilbe Granat* (deep pink), *A. Gunther* (pale pink) and *Beanty of Codsall* (creamy white) are three good sorts. Messrs. Isaac House and Sons staged a large collection of their perennial Scabions in named varieties, and in the gallery had many spikes of *Kniphofia* Mollender's Mount Etna, a valuable aloides (*Uvaria*) variety of bright coral pink colour.

Mr. E. Scaplehorn had an excellent general collection. At the corner, the reddish heads of *Sanguisorba rubra* flowers attracted a deal of attention, as also did the large vase of *Belladonna Lilies*.

A large group arranged by Mr. Amos Perry contained plants of *Monarda didyma*, hybrid Pentstemons and *Kniphofia*, set with considerable skill among the paler-flowered plants, particularly the Asters and *Heleniums*. He had a good patch of the dwarf *Solidago missouriensis*, which has much the appearance of a spreading, small-flowered yellow Michaelmas Daisy. In fact, the species was also shown by Mr. F. G. Wood under the name *Aster hybridus luteus*, the name under

which, only last year, it obtained an award of merit. Mr. Wood had various other interesting plants, such as *Physostegia altissima*, *Primula capitata Mooreana* and the dwarf blue *Campanula Bellardii* (pusilla).

The relatively large, shining purple fruits of the trailing little shrub *Billardiera longifolia* attracted a deal of curious attention in the exhibit of Messrs. W. H. Rogers and Son, where the shining scarlet berries on the dwarf plants of *Skimmia oblata nana* were highly decorative.

Chief among the comparatively few alpines in flower was a large pan of a very dark blue form of *Gentiana acaulis* shown by Mr. W. Wells, jun., who placed near it the dwarf *Gemma Borisii*, bearing plenty of orange-scarlet flowers. Mr. E. Dixon had a few plants of the dwarf *Campanula Spetchley* bearing white bell-shaped flowers, and Mr. A. J. Hall had a large batch of the small-flowered *Campanula Hallii*; while Messrs. Bowell and Skarratt included *Arabis rosea splendens* in their collection.

A very interesting collection of alpines in pots and pans was arranged by Mr. G. G. Whitelegg. Saxifrages were the most numerous, and these included some rare crusted and mossy varieties. He also had exceptionally good dwarf *Dianthus*es and *Primulas*. In a neat rockery Messrs. Maxwell and Beale planted a variety of dwarf *Ericas* with other appropriate plants.

Other exhibitors of hardy plants were Messrs. G. Gibson and Co., who had a large batch of Iceland Poppies of glowing orange yellow colour; Messrs. William Artindale and Sons; Messrs. Waterer, Crisp and Son, who displayed Michaelmas Daisies, *Gladioli*, etc., the Asters mostly, if not entirely, as growing; Messrs. B. Ladhams, Limited, who included such useful tall *Lobelias* as Mrs. Humbert (rose pink), *Salmon Queen*, *Purple King* and *Queen Victoria* (crimson); Messrs. William Cutbush and Sons, who had a large circular group of Michaelmas Daisies, Dahlias and Pentstemons; and Mr. Viger.

Mr. James MacDonald made another of his most fascinating grass gardens. The beds, shaped in rich green turf absolutely free from weeds, contained many elegantly graceful taller Grasses.

DAHLIAS

That losses by early frosts were not general is fully evident from the large collections of gorgeous Dahlias that many growers were able to arrange. These provided a wealth of colour that is not attainable by any other outdoor plant. The newer miniature Peony-flowered type which produces an abundance of bloom throughout the now long season was freely shown. These are all graceful flowers of good useful size and carried on sufficiently long stiff stems. The newest and best varieties are such as *Rainbow*, *Conspicua*, *Lovely*, *Neville* and *Dazzle*, which were seen in the fresh and bright display of Mr. J. T. West; while Mr. J. B. Roding included *Fairy*, *Rhoda*, *Glut*, *Halley* and *Glory of Stanhaus* in his representative exhibit of the autumn flower.

For those who prefer larger flowers of the same intense and varied colours there were the huge Decoratives and Peony-flowered varieties. Mr. Charles Turner set up noble stands of *Orange Boven*, *Phidias* and *Toreador*; while Messrs. William Treseder, Limited, illustrated the decorative value of such big blooms as *Roy Hay*, *Aglaia*, *Ebor*, *President Wilson* and *Mrs. Hay*.

A few years ago it was thought that the shapely Show and Fancy Dahlias were consigned to oblivion and would be no more seen, but it is evident that these varieties still have their admirers, for in addition to a good collection, shown in the time-honoured method on boards, Messrs. Dobbie and Co. shewed how valuable they are when tastefully arranged, a dozen or so together, in large vases with appropriate foliage. The varieties Mrs. Langtry, *Model* and *Warrior* were very fascinating in their regularity of form and beautiful colouring. The formal but dainty little Pompons also seem to be undergoing a revival, and for small vases and for such other purposes as dinner-table decorations these are especially valuable. There were charming little vases of *Bacchus*, *Mars*, *San Toy*, *Johnnie*, *Ideal* and *Censor* in Mr. Turner's collection, while other exhibitors also shewed very good varieties.

"MR. JAMES MACDONALD MADE ANOTHER OF HIS MOST FASCINATING GRASS GARDENS."

Among the group, Collarette varieties Mrs. Evans and Mrs. Perry, shown by Messrs. Treseder, Limited, stood out as being especially useful for filling small vases. The former is a round-shaped, scarlet crimson and the latter is a scarlet with a little white on some of the short quills. Such Collarettes, of the usual size, as Hussar, Strathmore, Arran and Glenoe were also well shown. Messrs. J. Cheal and Sons shewed many of their highly decorative Star varieties and some perfectly formed show Singles of charming colouring; while Messrs. Carter Page and Co. had a number of Cactus varieties which are good garden plants as well as furnishing exhibition blooms.

The centrepiece of Rose Supreme, a lovely, cosy mauve miniature Peony-flowered Dahlia, in a contribution by Messrs. Jarman and Co. was particularly successful, and near by they had a goodly number of Joyce Goddard, a larger bloom of yellow colour heavily flushed with orange scarlet.

CARNATIONS

Carnations in great beauty were attractively set out by Messrs. Allwood Brothers, who had a large stand of their new bluish salmon George Allwood near the vividly coloured Edward Allwood. Wivelsfield Claret, Maine Sunshine and Wivelsfield Apricot are also well worth especial attention. On a considerable floor space Messrs. Allwood Brothers made a pretty grass-bordered garden of uncommon design with their free-flowering *Dianthus Allwoodii*. There they tastefully massed Beatrice, rose madder coloured; Barbara, crimson; Brian, salmon pink; and Jeanne, bluish pink. To relieve the levelness they grouped some excellent perpetual Border varieties.

An imposing group of the Perpetual-flowering Carnations which may be relied upon to give a maximum quantity of good flowers were exhibited by Mr. C. Engelmann in great quantity. Among the brightly coloured sorts we noted Tarzan, Aviator and Belle Washburn. Those of pink shades included Dora, Delice, Luchantress Supreme and Laddie, while there were many others of white and various shades of colour.

Chief among the varieties shown by Messrs. Stuart Low and Co. were Red Ensign, Lord Lambourne, White Pearl and Eileen Low; while Messrs. Keith Luxford and Co. grouped Bona, salmon; Mrs. Walter Heims, pink; Cheerful, rosy crimson; and Tangerine.

STOVE and GREENHOUSE

Stove plants were very few and practically restricted to a group of such useful Palms as *Phoenix rupicola* and *Cocus flexuosa* with *Phoenix canariensis*, *Kentia Belmoreana* and *K. Fosteriana* displayed by Messrs. Robert Green, Limited, who also shewed in another place a large collection of Bay trees. Messrs. Stuart Low and Co. had pot plants of the fragrant *Bouvardia Humboldtii*, *Chiroma ixterea* interspersed with *Acacias*.

Other varieties of *Bouvardia*, associated with *Cyclamen persicum*, *Primula obconica*, Ferns and varieties of the shrubby *Veronica speciosa*, were staged by Mr. E. H. Canser; while Mr. R. J. Case had good trusses of single and double flowered *Zonal Pelargoniums*.

A very interesting collection of Cacti and other succulent plants was arranged by Mr. Sidney Smith. These were mostly in the form of the fascinating little plants one sees in shop windows, but he also had larger specimens of such genera as *Cereus*, *Opuntia* and *Euphorbia*. Among the smaller ones were *Mammillarias*, *Echeverias* and *Sempervivums*.

Fresh and sweet Violets in quantity were exhibited by Mr. B. Pinney and Mr. J. J. Kettle, while Mr. Ernest Dixon had an attractive model of a sunken garden with an adjoining rockery.

ORCHIDS

A gold medal was awarded to Messrs. Charlesworth and Co. for a very fine collection of Orchids. Orchids were also well shown by Messrs. Stuart Low and Co., Messrs. Flory and Black, and Messrs. Mansell and Hatcher.

NEW AND RARE PLANTS

The awards to novelties included awards of merit to *Chrysanthemums* Doreen Woolman, Minstrel, Mrs. Jack Pearson and Royal Salute, which received recognition on the previous day at the meeting of the National Chrysanthemum Society, and are described on the opposite page.

Aster Snowdrift.—A very useful variety of erect yet graceful habit of *Novi Belgii* type. It bears plenty of almost fully double white flowers with narrow florets. Award of merit. Shewn by Mr. E. Ballard.

Buddleia Golden Glow.—This is one of the comparatively recent hybrids between *B. globosa* and *B. variabilis*. The influence of the former

is well flushed. Award of merit. Shewn by Mr. W. Van de Weyer.

B. Moonlight.—This is a creamy-coloured counterpart of the above. Award of merit. Shewn by Mr. W. Van de Weyer.

Berberis Autumn Beauty.—A beautiful rubro-stilla variety which has small apple-shaped berries of creamy green colour which ripen to bright coral red. The tints of the various stages of development contrast well. Award of merit. Shewn from the R.H.S. Gardens, Wisley.

Gladiolus Palestine.—A very handsome large-flowered hybrid of creamy white colour with vivid crimson markings on the lower segments. Award of merit. Shewn by Messrs. Kelway and Sons.

Ligustrum Quihoui.—An uncommon and graceful Privet which produces very long, erect, spikes of white flowers. The stems are greyish and furnished with narrow dark green leaves. The fragrant flowers are followed by shining purplish fruits. It is a native of China. Shewn by the Hon. Vicary Gibbs.

Brasso-Cattleya maculata The Dell Variety.—A handsome flower bearing the large frilled lip associated with the *Brassovolas*. All the floral parts are substantial; the sepals and petals are a rich golden colour, the lip is veined with rose and the waved margin is lightly flushed with purple. Award of merit. Shewn by Baron Schröder.

Cattleya Aeneas var. Goliath.—The sepals and petals are a lovely golden buff colour. The lip is waisted and widens at the end. It is beautifully lined with carmine. Award of merit. Shewn by Messrs. Cowan and Co.

Laelio-Cattleya Marina var. majestica.—An exceedingly handsome bloom. The large, spreading sepals and petals are an uncommon and fascinating mauve purple. The broad lip has an unusual band of yellow midway and the outer portion is coloured a gorgeous velvety purple. First-class certificate. Shewn by Messrs. Cowan and Co.

Sophro-Laelio-Cattleya His Majesty.—The sepals and petals bright rosy mauve with gold shading, the petals banded with purple; the lip is a rich ruby, with a bright yellow disc. Award of merit. Shewn by Messrs. J. Charlesworth and Co.

Laelio-Cattleya Mrs. Medo var. Sovereign.—Of clear canary yellow colouring, which contrasts with a large velvety crimson labellum, of which the front is extended in a narrow lobe as in

MINIATURE PEONY-FLOWERED DAHLIA KITTY, ROSE MAUVE AND CRIMSON.

is seen in the round heads of flowers and the ovate lanceolate dark green foliage, which is silvery beneath. *B. variabilis* is apparent in the erect sprays of branched flowers and their fragrance. The colour of the little round blossoms is yellow with an orange eye. The unopened buds are

Cattleya Iris. Award of merit. Shewn by Messrs. Stuart Low and Co.

Cattleya Tagus var. Cupid.—A large and shapely flower of clear yellow colouring with a crimson lip. Award of merit. Shewn by Messrs. Flory and Black.

NEW DAHLIAS.

The Joint Dahlia Committee sat for the last time this season, and from fifteen seedlings selected the following for trial at Wisley next season.

Carine.—A small Decorative bloom of star-like form nearly approximating a Cactus variety with stiff straight florets. It is pale orange in colour and highly decorative.

Defoe.—A large Decorative variety of perfect shape and charming silky rose colouring.

Iona.—This is a brilliant medium-sized Decorative of brilliant scarlet colour with a yellow reverse. As there already is an Iona, the name is to be changed.

Kitty.—A pretty little miniature Paeony-flowered variety which is almost a roundish Star variety. The flowers are a bright rosy mauve with a rich crimson zone. All the above were shown by Messrs. Burrell and Co.

NEW

CHRYSANTHEMUMS.

The Floral Committee of the National Chrysanthemum Society met at the Holland Park Hall on Monday, October 1, and gave awards to the following new early-flowering varieties:

Doreen Woolman.—A very bright single-flowered variety of Mensa type and size and terra-cotta colour with a suggestion of apricot. First-class certificate.

Minstrel.—An attractive dwarf variety of especial value in the undisbudded state. The flattish, fully double flowers are of reddish crimson colour. First-class certificate.

Purple Amaranth.—An attractive flower of its name colour, with a dull silvery reverse. Card of commendation.

Purple Flag.—A quite dwarf variety of compact form. The colour is rich crimson, flushed with purple maroon. Card of commendation.

Royal Salute.—An exceedingly effective bright chestnut red variety which is equally suitable for disbudding or for growing naturally. The form and habit are very good. First-class certificate.

Shirley Terra-cotta.—A good single-flowered variety of good medium size and made up of plenty of narrow florets of deep terra-cotta colour. First-class certificate. All the above were shown by Mr. H. Woolman.

Mrs. Jack Pearson.—A most useful bright orange bronze coloured variety of dwarf habit which flowers from mid-July until cut by frosts. First-class certificate. Shown by Mr. Philip Ladds.

September Yellow.—A valuable sport from September White and, like that variety, is larger

than the average dwarf border Chrysanthemum and bears plenty of perfectly formed blooms. The colour is a soft yellow. First-class certificate. Shown by Mr. David Inghamells.

NEW FRUITS.

The Fruit and Vegetable Committee did not make any award to novelties but considered the

APPLE JOHN WATERER, WHICH IS SAID TO BE AN EXCELLENT CROPPER.

(Note the penny above to show comparative size.)

merits of several seedling Apples, a Strawberry, and Grapes.

Apple Comrade. shown by Mr. F. C. Stoop of West Hall, Byfleet, appeared to be the only variety entered for the Bunyard Cup, but the Committee, while recognising its merits, thought it too like James Grieve, and therefore no advance on older varieties.

Apple John Waterer.—This gigantic fruit, which in appearance strongly resembles a gigantic Lane's Prince Albert, being flattish in shape, but symmetrical and, as shown, of medium green colouring. The foliage is stout and healthy-looking. Apart from its extraordinary size it is, we understand, a very heavy cropper. Shown by Messrs. J. Waterer, Sons and Crisp.

Strawberry Boreal Giant is said to be a truly perpetual bearer, and is to be tried at Wisley. It is in flower and in fruit at the present time. The trusses are very large and the small, round fruits are dark red and of satisfactory flavour. Shown by Mr. Robert Holmes, Norwich.

Mrs. T. S. Hall, Criche St. Thomas, Chard, sent a bunch of Grapes which is somewhat like Mrs. Pince, and is to be asked to send cuttings to Wisley so that it may be tested there.

LIST OF AWARDS

CHALLENGE CUPS.

Coronation Cup.—The Hon. Vicary Gibbs (gardener, E. Beckett), for the most meritorious group.
Sutton Cup.—The Rev. J. Davies, for the best collection of vegetables.
R. H. S. Cup for Vegetables.—Mr. R. Chetwynd Stapylton, for the competitor who secures the greatest number of first prize points.
Affiliated Societies' Cup.—East Anglian Horticultural Club, for the best exhibit of fruit by an affiliated society.
Wagon Cup.—G. Prince, for the best exhibit of Roses.
George Monck Cup.—Mr. W. H. Thickett, for the best exhibit of Grapes by an amateur.

CHRYSANTHEMUMS AND DAHLIAS.

Large Silver Cup.—Hobbie and Co., for Dahlias.
Small Silver Cups.—K. Luxford and Co., for Chrysanthemums; C. Turner, for Dahlias.
Silver-gilt Flora Medals.—Carter Page and Co., J. B. Tiding, W. Tieseler, Limited, and J. F. West, for Dahlias.
Silver-gilt Banksian Medals.—Jarmen and Co. for Dahlias; William Vandell, for Chrysanthemums.
Silver Banksian Medal.—J. Cheal and Sons, for Dahlias.

GREENHOUSE FLOWERS, ETC.

Large Silver Cup.—C. Engelmann, for Carnations.
Small Silver Cups.—S. Smith, for Cacti; Blackmore and Langdon, for Begonias, etc.; L. B. Russell, Limited, for Clematis and stove plants.
Silver-gilt Flora Medals.—Allwood Brothers and Stuart Low and Co., for Carnations.
Silver-gilt Banksian Medal.—Allwood Brothers, for group of Carnations.
Silver Flora Medals.—E. H. Causser, for Cyclamens, Primulas, etc.; K. Luxford and Co., for Carnations.

SHRUBS.

Large Silver Cup.—Billier and Sons, for conifers, hardy trees, shrubs, etc.
Small Silver Cups.—J. Cheal and Sons, for ornamental shrubs; G. Renthle, for hardy plants; R. Wallace and Co., for shrubs.
Silver-gilt Flora Medal.—A. Charlton and Sons, for hardy trees and shrubs.
Silver-gilt Banksian Medals.—R. and G. Cuthbert, for conifers, flowering shrubs and Ericas; Clarence Elliott, Limited, for dwarf shrubs.
Silver Flora Medals.—Robert Green, Limited, for Palms and Bay trees; John Klinkert, for clipped Yew and Box trees in tubs.
Silver Banksian Medal.—W. H. Rogers and Son, for shrubs.
Silver Lindley Medal.—Billier and Sons, for rare plants of special interest.

FRUIT (NON-COMPETITIVE GROUPS).

Gold Medal.—G. Bunyard and Co., Limited.
Large Silver Cup.—Barnham Nurseries, Limited.
Small Silver Cup.—Daniels Brothers, Limited.
Silver-gilt Hogg Medal.—Stanley College.
Silver Hogg Medals.—Horticultural College, Swanley; S. Spooner and Son; E. A. Watts.

HERBACEOUS, ETC.

Large Silver Cup.—R. Wallace and Co., for hardy plants.
Small Silver Cups.—Bowell and Skarratt, for alpinas, etc.; G. Jackman and Son, for Clematis and hardy plants.
Silver-gilt Flora Medals.—Isaac House and Son, for Scabiosa caucasica; Ernest Ballard and H. J. Jones, for Michaelmas Daisies; John Waterer, Sons and Crisp, for herbaceous plants; Dickson and Robinson, for Michaelmas Daisies; Amos Perry, for hardy plants and Ferns; Harkness and Son, for hardy flowers; R. Bath, Limited, for Gladioli.
Silver-gilt Banksian Medals.—W. H. Rogers and Son, for alpinas, etc.; Maxwell and Beale, for hardy plants and alpinas; W. Artindale, Bakers, Limited, William Cuthbert and Son, Limited, and W. Wells, Jun., for hardy plants; Alva J. Hall, for Campanulas, etc.; Lowe and Gibson, for Gladioli.
Silver Flora Medals.—F. G. Wood, for rock and hardy plants; P. Ladhams, Limited, for Lobelias; Blackmore and Langdon, for Michaelmas Daisies; Thomas Carlike, for hardy plants; Dobbie and Co., Limited, for Sweet Peas; Kelway and Son, for Gladioli; G. Gibson and Co., for hardy plants.
Silver Banksian Medals.—G. G. Whitelegg, for alpine plants in pans; E. Scapellato, for herbaceous; J. J. Kettle and B. Pimney, for Violets; Central Garden Supplies, for Violas, herbaceous, etc.; John Forbes (Hawick), Limited, for hardy plants; H. Vigers, for Delphiniums.
Silver-gilt Flora Medal.—James MacDonald, for Grasses.

ROSES.

Large Silver Cup.—George Prince.
Small Silver Cups.—W. E. Chaplin, Elisha Hicks and John Matlock.
Silver-gilt Flora Medals.—B. R. Cant and Sons and D. Prior and Son.
Silver-gilt Banksian Medal.—Alex. Dickson and Sons.
Silver Flora Medals.—The Rev. J. H. Pemberton and John Waterer, Sons and Crisp.

ORCHIDS.

Gold Medal.—Charlesworth and Co.
Large Silver Cup.—Stuart Low and Co.
Silver-gilt Flora Medals.—Flory and Black and Mansell and Hatcher.

VEGETABLES (NON-COMPETITIVE GROUPS).
Gold Medals.—The Hon. Vicary Gibbs (gardener, E. Beckett) and Sutton and Sons for vegetables.

Large Silver Cup.—Dobbie and Co., for Potatoes.
Silver Knighton Medal.—H. Chapman, Limited, for vegetables.

FRUIT TREES IN POTS.

Large Silver Cup.—J. C. Allrove, for fruit trees in pots and fruit.
Small Silver Cup.—John Waterer, Sons and Crisp, for fruit.
Silver-gilt Hogg Medal.—T. Rivers and Sons, for fruit trees in pots.

ROSES FOR THE SHRUBBERY

KIX gardeners with ample space at disposal not infrequently devote a section of semi-wild garden to Rose species and to garden varieties which have a sufficiently wild appearance. This type of Rose never looks better than when finishing the shelving sides of a little valley. Whether the valley be wholly natural, or the result of excavation for clay, marl, gravel or sand, or made specially for the occasion, matters not a jot. Not everyone is sufficiently enamoured of this type of Rose to provide a special garden for it, but none of us who loves shrubs can afford to neglect the possibilities of the great genus *Rosa* which provides as many beautiful and attractive shrubs (shrubbery shrubs, if we may say so) as any other genus whatsoever. There will, indeed, be few to dispute that it eclipses all other genera in this respect!

Roses for the shrubbery divide themselves naturally into two great classes. The first group includes all the suitable species and varieties which make self-supporting bushes; the other comprises those of rambling habit which, like the Dog Rose and the Sweet Briar, depend very largely upon the support of other shrubs and trees.

Taking the groups in the order given, we have a large number of species which are beautiful in growth, charming when in flower and handsome when in fruit. Some of the best large growers are *R. macrophylla*, *Moyesii* (including *Fargesii*), *Hugonis*, *rugosa*, *pomifera*, *sericea* and *omniensis* (or *sericea*) *pteracantha*.

⚔ Rather smaller than the foregoing but still large enough for the middle planting in a shrubbery are *R. rubrifolia* (ferruginea), *spinosissima* (several forms) and *altaica*. Of quite dwarf kinds, the forms of *Rosa lutea* and *R. nitida* are representative.

Dealing first with the larger growers, *Rosa macrocarpa* may be taken as typical of the species with bottle-like fruits. This peculiar appearance is caused by the persistent flower-calyx projecting, almost like the cornea of a chimney-stack, above the narrowed neck of the hip. The blossoms are deep rosy red in colour. *R. Moyesii*, with similar fruits, is quite distinct, has almost fern-like foliage and flowers of a lurid red, quite unique in the genus and, as far as we know, unmatched in any other flower. The plant with deep rose-coloured flowers, known and listed as *R. Fargesii*, has proved to be nothing more than a variety of *R. Moyesii*, and plants with flowers of the two very distinct colourings may often be raised from seeds taken from the same hip. The yellow-flowered *Rosa Hugonis* is quite dissimilar to those mentioned so far, but is a robust species with strong, arching growths. *Rosa rugosa*, the Ramanas Rose, with, typically, rose flowers with more than a hint of magenta, and a rather stiff and inelegant habit of growth, is noteworthy for its large sealing-wax red apple-like fruits, which, unless taken by birds, persist for some time. There is a pure white form which fruits as freely as the type, and a number of double forms and hybrids, which, of course, do not fruit. *Blanc Double de Coubert* is a typical *rugosa* with double white blossoms, but

Conrad F. Meyer, with long arching canes and large fragrant blossoms is a hybrid. Very early to flower, it bears its pretty silvery rose blossoms freely, and these are very handsome and shapely when partially expanded. *Nova Zembla* is supposed to be an albino of Conrad F. Meyer, but is not pure white, being, indeed, a very pale silvery rose, which, especially near towns, is apt to look uncommonly like dirty white. *Rosa pomifera* with very bristly fruits is closely akin to the Ramanas Rose. *Rosa sericea* makes a good very thorny bush covered with white flowers, but is overshadowed in gardens by the plant generally known as *R. s. pteracantha*, but which the botanists tell us is really a form of the somewhat similar *Rosa omniensis*. This also has white flowers, but is chiefly noteworthy for the very large and decorative crimson semi-translucent thorns.

Rosa rubrifolia is particularly noteworthy for its curious reddish-greyish-blue foliage. The deep rose flowers are produced over a considerable period, but comparatively few are open at any one time. The trusses of crimson hips, however, are very attractive in autumn. There are several distinct forms of our native Burnet Rose, *R. spinosissima*, in commerce, mostly with white, but some with yellow flowers, which rival in brilliance the Persian Yellow. *Rosa altaica* with yellow blossoms is very near akin botanically to *R. spinosissima*. *R. lutea* is represented by three very distinct colour forms known respectively as the Austrian Yellow, the Persian Yellow and the Austrian Copper. These are too well known to need description. This species has been used very successfully for introducing new colouring into bedding Roses. All the race of Pernetiana hybrids owe their rich colouring to this species, and many of the richly coloured Hybrid Teas which are now introduced yearly owe their vivid colouring to an original infusion of *R. lutea* "blood."

Apart from species and their immediate derivatives, there are many Roses which make handsome

bushes for the shrubbery. Conrad F. Meyer has already been mentioned. *Alister Stella Gray* (a *Noisette*, but hardy for its class) is another. The rather stubborn growths of this variety really make it unsuitable for arch or pergola, but as a free bush it is truly grand. The small but shapely blossoms, which are borne in trusses and open bright yellow, quickly fading to cream, can always be gathered from early summer until late autumn. We have gathered a not despicable posy of them on New Year's Eve.

There is a whole range of Lord Penzance's Hybrid Sweet Briars, all beautiful and fragrant, and every one suitable for making bold bushes in the shrubbery. Where space is ample these are even more effective in groups than when single plants are employed. A few of the very best include *Meg Merrilies*, *Rose Bradwardine*, *Julia Manning*, *Lord Penzance* and *Lady Penzance*. The last two are smaller growers, but very beautiful and uncommon with their fawn-shaded blossoms. Yet another single Rose which makes a splendid free bush is the multiflora *Leuchtstern*, which is a very long-lived as well as a very showy Rose. The "Irish" singles typified by *Irish Elegance* are also more suitable for the shrubbery than the rose garden. Other suitable kinds include the crimson *Grüss an Teplitz* and the China (should not it rather be Hybrid China?) *Mme. E. Rœsal*.

To the second class—those, it will be remembered, suitable for climbing through and trailing over other shrubs—belong *Rosa multiflora*, represented in gardens by the pretty white-flowered *R. polyantha simplex*, and all its hybrids, including *Crimson Rambler*—better in a shrubbery than anywhere—*Blush Rambler*, *Agliaia*, *Thalia*, *Hélène* and so forth. The Musk Rose, *R. moschata*, a variable species best represented in gardens by *R. Brunoni*, is a taller grower and loves to throw its shoots through the branches of fair-sized trees. A beautiful hybrid of this species with double white flowers and known as *The Garland* is a little less rampant, and so perhaps more useful for the average shrubbery. Two new varieties of this Hybrid Musk race raised by the Rev. I. H. Pemberton, and known respectively

THE BEAUTIFUL WHITE HYBRID MUSK ROSE THE GARLAND, WHICH IS HAPPIEST TRAILING OVER SHRUBS.

ROSE HELENE IN THE ROSE DELL AT KEW GARDENS.

as Nur Mahal and Aurora, the former with rosy crimson and the latter with soft yellow blossoms, should also, though less rampant, be good for the shrubbery.

Where the shrubbery forms a shelter belt from

east winds the white-flowered but not very hardy *R. sinica* should find a place, and the shelter of other shrubs will be grateful to it. Its beautiful pink derivative known as *R. sinica Anemone* will also appreciate a similar spot.

BUSH FRUITS

Where to Plant and How to Grow Them.

THE English language, often ambiguous, is especially so when referring to fruit bushes. Bush fruits, properly speaking, as grown in this country consist of the Gooseberry, and the Red, White and Black Currants. To these, though the canes are only of a year's duration, the Raspberry is often added, and even, at a push, the Strawberry. There is here no ground for confusion, however. This arises because certain tree-fruits, notably the Apple and Pear, are frequently trained in bush form, so that when fruit bushes are referred to, one is sometimes at a loss to know what is in mind. The brief notes which follow have reference to bush fruits properly so called.

It is customary to devote a section of the kitchen garden to bush fruits, keeping the different kinds as close together as possible. In some cases the idea, unquestionably, is to enclose them all in a cage as a protection from birds. It is, naturally, cheaper to build one large cage to include all the kinds than to erect several smaller cages for the different species. Even where such protection is neither afforded nor contemplated, however, the various kinds are usually kept together none the less, and in nine cases out of ten this is a mistake. Nor do I think that, in the average garden, the advantage of caging presents an adequate excuse for growing Black Currants, Red Currants and Raspberries side by side. Their requirements are so different. The Black Currant likes a rather stiff, damp, rich, even gross rooting medium; the Red Currant, of which of course the White Currant is no more than a variety, prefers a fairly light, but moderately fertile soil; while the

Raspberry likes a rich loam which never gets really dry in summer, and never becomes stagnant in winter. Owing to the depredations of eelworm immediately the soil becomes sour, the Raspberry plantation should be treated to frequent and fairly heavy dressings of lime.

It is obvious that the natural conditions which will suit these three important fruits are not very likely to lie side by side. Undoubtedly it does happen sometimes with a new garden that there is nothing to choose as regards soil or situation, between top and bottom, left and right. Even then a place may usually be found for the Black Currants apart, especially if the house is in the depths of the country (see the next paragraph). Generally speaking, though, some parts are moister than others, and there are corresponding differences in the sweetness and fertility of various sections.

The Black Currant has the ability to utilise large quantities of sewage, and this not only in summer, but in winter. A situation in close proximity to a pump from a dumb-well is therefore excellent from the gardener's point of view, and also disposes of the very common difficulty of what to do with the scum and solids when the tank comes to be cleared out. The Black Currant has proved useful, too, in connexion with the direct disposal of sewage. There are many sites in country districts where very little fall is available for the treatment of the house sewage. Purification before discharge into a brook or drain then becomes something of a problem. The effluent may in such case be much improved by planting Black Currant bushes over a series of parallel rubble-filled drains through which the sewage

must slowly pass on its way to the outlet. It is not, of course, suggested that the Currant bushes alone will act as efficient sewage purifiers, but that they may be made of great assistance is beyond question.

In such places a maximum amount of stem and foliage will be the aim, but where the only object in view is the production of heavy crops of first-rate fruit, the still rather unusual method of training the young growths to wires, exactly as Raspberries are commonly trained, should find favour. Cuttings or young trees are planted in lines about 2 ft. apart in the line. The lines may, with advantage, be spaced widely, leaving room between for not too tall-growing vegetable crops. Every year all but the current season's growth is removed after the fruits are gathered, and the young growths themselves are reduced to three or four, leaving just sufficient, in fact, comfortably to furnish the training wires. The best height for the wires will depend to some extent upon the variety grown and, even more, upon the nature of the soil and the assistance afforded during growth. As a rough guide, however, two wires, one 1 ft. from the ground and the other 2 ft., will, as a rule, suffice. Good fruit may be obtained by this method from comparatively poor ground; but, if only for the sake of the permanence of the planting, it is well to "do" the plants as well as possible. Now as to varieties, the best all-round Black Currant is generally allowed to be Boskoop Giant. It is, however, a mistake to rely upon one variety, as bad weather at flowering-time sometimes causes an almost total failure of the crop. By growing two or more varieties which flower at different seasons, this danger may be largely overcome. Other good varieties are Black Naples, rather early; Carter's Champion, main-crop; and Daniel's September Black, very late. The last named is worth growing if only because of its season of fruiting, but it is, in fact, a fine grower and excellent cropper.

The Black Currant, which was formerly a very clean-growing bush, has of late years been attacked by two very troublesome diseases. "Big-bud," caused by the ravages of a minute parasite—the black currant mite, *Phytoptus ribis*—is most difficult to control once it makes headway, but if a sharp look-out be kept and the characteristic swollen and blunted buds be picked off and burnt as soon as they shew themselves, it may be kept down with little difficulty. The newer pest, known as "reversion," in which the bushes produce a distinct and weedy type of foliage, will probably be found to be due to eelworm attacks. Bushes so affected should be promptly destroyed and great care should be taken not to propagate from plants shewing the slightest tendency to "revert."

We have seen that the pruning of Black Currants should consist of removing old wood, leaving the strong new shoots, which under proper conditions of culture and pruning are regularly produced from the base, to bear the crop of fruit. The natural growth of the Red Currant is entirely different. It is usual to grow this fruit on bushes with a "leg." A short leg not exceeding, say, 1 ft. is most profitable, but "standards" with legs some 3½ ft. or 4 ft. in height are easy to gather from, and to protect from birds, and quite practicable. For training upon walls, cordons are very useful as well as picturesque, but the Red Currant may be trained fan-wise, or even as an espalier if desired. The pruning is not very dissimilar to that of an Apple on a dwarfing stock. Like the Apple, the Red Currant bears its fruit on spurs upon matured wood. The production of growths from below ground is discouraged, in the first instance, by the removal of all buds on the cuttings below ground level. This does not, of course, prevent the production of coarse growths (water shoots) from

the centre of the tree, but these should be removed as soon as seen, preferably while they may still be nibbled out with finger and thumb. Leaving out of account such "water shoots" strong wood should be encouraged in the bushes, and weaker, spent wood be gradually removed. Stopping and thinning in summer (summer pruning) so that all the sunlight and air possible may reach the shoots is important. In winter shorten back the leading shoots to a length of not more than oins., cutting, of course, to an eye pointing outwards. A distance of 6 ft. should be allowed from centre to centre of the bushes, and if more than one row is planted

they may with advantage be arranged quincunx fashion, utilising bushes of White Currants to fill in the vacant spaces at the ends of the alternate rows, for the pleasantly flavoured White Currant is, like most albinos, not so strong a grower as the more typical red varieties. Red Currants do quite well against a north wall, and not only do their fruits ripen later there, but they hang a considerable time in perfection on the bushes and so lengthen considerably the season of this useful fruit. Out in the open, summer mulching is very beneficial, and if stable litter is available for this purpose, so much the better.

Some of the best varieties are given below, but different sorts give most satisfaction in gardens on apparently similar soils, so that it is well to experiment a little. Cherry is early, large and prolific; Red Dutch is well known as a good mid-season kind and a heavy bearer; Ruby Castle, rather later, is perhaps the most popular sort at present, bunches and fruits are both large and it remains for some time in condition; Mammoth and La Constante are two good late sorts, the last named being the latest of all—both have fine fruits. White Dutch is the best white variety. R. V. G. W.

(To be continued.)

A GARDEN OF CHARACTER AND CHARM

THREE years ago there lay hidden by a thick belt of tall Poplars just behind the quaint little railway station at Market Bosworth, Leicestershire, an old disused and deserted brickyard. The great pits, from which thousands of tons of clay had been excavated, had filled with water, Sedges and Bulrushes had established themselves, and the banks were overgrown with coarse Grasses, Briars, Brambles and seedling Thorns. The place was a convenient tip for all manner of rubbish, and a happy home of water rats and vermin.

Mr. Frank Bouskell, one of our keenest and most successful amateur hardy plantmen, for some time chairman of the National Hardy Plant Society and now president of the Society's Council, realised the possibilities of this spot, and having acquired it, he devoted himself to the delightful, although somewhat arduous task of converting

Apart from a judicious and altogether necessary clearance of Brambles and scrub that impeded passage, there has been little interference with the natural features of the place, but at intervals along a meandering pathway between the boundary trees little gaps have been opened up, through each of which a glimpse may be had of some particular feature, and a different view obtained of the water or of some strikingly beautiful drift of flowering plants or other appropriately introduced subject. Wherever light has thus been let into this shady walk one finds Rambler Roses or Clematis montana growing rampant over some old tree stump, and in every little recess or clearance some native plant of distinctive merit has been introduced to grow in a setting as natural as could be found.

There has been no making of beds of formal design or any such artificiality as pergolas or rustic arches, but from the entrance gates there

notice our approach to a building. Perhaps the most remarkable thing about these herbaceous borders is the large percentage of plants that are seedlings, crosses and selections of Mr. Bouskell's own raising, and not only do we note differences between them and the varieties familiar to us in nurseries of hardy plant specialists, but in many cases we find them superior to most of the varieties we know, for Mr. Bouskell has the fine judgment of a connoisseur and exceptionally successful exhibitor of over thirty years' experience to guide him in his selections and rejections. Of *Pentstemon barbatus* he has one of a bright coral pink shade totally different from the ordinary reds and scarlets. An Oriental Poppy which he has named Bosworth Park not only possesses a wonderful shade of deep salmon pink, but comes into bloom long after the rest of the tribe have gone to seed. The number of hybrid *Verbascums* is too great to permit of detailed description, for this family has for years occupied Mr. Bouskell's special attention. A form of *Lythrum virgatum* with flowers many degrees brighter than the best I have seen elsewhere was making a wonderful blaze of colour, and so, all along these extensive borders, might be seen extra good forms of first one plant and then another.

From the front of the bungalow the ground falls away with a long steep descent right down to the water's edge, and this great bank has been recently converted into a rockery. It is necessarily "new" at present, but it has been cleverly planted with a comprehensive assortment of alpine plants, with stretches of hardy *Ericas* and well placed groups and clumps of flowering shrubs, dwarf-growing conifers, and trailing alpine and Wichuriana Roses. Here, again, we find a highly interesting display of home-raised seedling forms and hybrids of such things as *Cheiranthus*, *Linaria*, *Oenothera* and *Dianthus*; while of scarce and interesting native plants there are upwards of 200 kinds, most of which Mr. Bouskell has himself gathered from their wild haunts in various parts of England and Ireland.

Of British Orchids many are well established, and some have been successfully raised from seed.

The margins of the ponds demand attention, for here we find broad masses of the finest *Astilbes* throwing up great feathery plumes of bloom ranging in colour from silvery white and cream through delicate flesh pinks to deep rose and reddish purple. *Lysimachias*, *Lythnums*, tall, handsome *Rumex*, *Eulalias* and a host of other bog plants mingle with the Reeds, Rushes and Sedges that grow with the abandon and luxuriance that betokens the ideal environment, and as we take up some point of vantage and cast our gaze over the rippling expanse of water we confront the crowning glory of great spreading masses of white and coloured Water Lilies. The strength and vigour of the *Nymphaeas* is remarkable. From

NYMPHAEAS AT SEDGEMERE, MARKET BOSWORTH.

this neglected waste into a garden according to his own conceptions and taste. Last month I paid what of late years has been an annual visit to Market Bosworth, and found what I can only describe as a wonderful transformation in this place, for there already exists a garden which in many respects is totally different from any other garden I know, and altogether delightful.

is a wide irregular and circuitous roadway, on either side of which run broad borders occupied by a bewildering variety of hardy herbaceous plants. This roadway brings us eventually to a substantially built and homely-looking bungalow with steep thatched roof, but we are so fully occupied with the infinite variety and gorgeous colour of the herbaceous borders that we scarcely

the mass of the giant white shewn in the accompanying illustration blooms were cut during my stay that measured 14 ins. across. Smaller plants of the best of Marliac's pinks and deep reds, with only a second season's growth, were throwing

a shrub and tree. Altogether one feels that Mr. Bouskell has achieved a triumph. He has made a garden exactly suited to its setting and environment, and in so doing has obtained something unique and soul-satisfying. He might at far

Kochiana excisa. But he found it impossible in the Continental climate to produce huge masses of the plant covered with such numerous flowers as appeared, e.g., in a bed in a garden at Blessington, Ireland. M. Correvon added that "*Kochiana* and *Clusii* are the antitypes, the one of the granite (calcifuge), the other the chalk loving. The three others are, or seem to be, indifferent as to lime." In nature, however, *G. angustifolia* usually grows on limestone. Descriptions were then given, and in that of *G. angustifolia* Vill. (= *sabauda* Boiss.) the very stoloniferous and creeping nature of the plant is emphasised. "The culture of it is the easiest possible, and I think it was originally the *Gentianella* which has altered in character under centuries of culture." I offer no solution, but M. Correvon was probably right in what he said. He knows these perplexing plants of the European mountains, and he knows from personal visits better than anyone on the Continent what alpine plants are cultivated in English gardens.

G. angustifolia was described by Villars in his "Hist. des Plantes de Dauphiné," 1787, Vol. II, page 526: "*Gentiana foliis oblongo linearibus enerviis, corolla campanulata caulem excedente*." His description begins with: "I believe with all botanists that these two plants [*G. acaulis* and *G. angustifolia*] are two not very distinct species, but as I have found the differences rather remarkable I have thought it suitable to separate them, whether they are taken as species or as varieties." Villars also first described *G. alpina*, and gave a good figure of it on (copper) plate x, loc. cit. This is also a stoloniferous and creeping plant, much smaller than the others of the group and, like *G. Clusii*, usually more or less stemless, so that they resemble in that particular the *G. acaulis* of Linné, who wrote on the type specimen now at Burlington House "*Gentiana caule unifloro flore campanulato caulem longitudine excedente*." The distribution of *G. angustifolia* Vill. is Savoy, Dauphiny, Provence, North Italy, rare in Southern Switzerland, Jura (?), Pyrenees. Mr. Ingwersen believes a lowland form of *G. excisa* to be the true origin of our garden plant. Will he or some other botanist examine in London any such specimens "from moorlands in Northern Germany and from what . . . is again Denmark"? Can we also be told how Dr. Murbeck arranges this group? Here in Bristol we have neither the specimens nor some of the literature to help us.

Those who wish for the original description of *G. excisa* Presl. will find it in "Flora" (1828), page 268; those of its synonym *G. Kochiana* Perr. et Song. and of *G. Clusii* Perr. et Song. in "Plantes nouv., rares et crit. Savoie," in "Bull. Soc. Hist. Nat. Savoie" (1853), page 33. Huxley's paper on "The Gentians: Notes and Queries" ("Journ. Linn. Soc.," 1888, page 101) may be read by those interested in the morphological relations, distribution and possible evolution of the beautiful plants of the family *Gentianaceæ*.—H. STUART THOMPSON.

A VASE OF DIGNITY AND IMPUDENCE.

"THE first and only yellow Michaelmas Daisy," as Amos Perry writes in his catalogue about his *Aster hybridus luteus* is a treasure. Although its small, soft, canary-coloured flowers individually feature in no small degree those of the *Senecio Jacobaea* (for which I think I can claim our local Cheshire name—see Holland and Britain—as being the most unsavoury and unfit for polite ears of all the fifty odd wherewith it has been so plentifully endowed), yet arranged as they are in little loose masses, they are "quite (as) all right" in small vases as the 2ft. high plants are in a border. The chance juxtaposition of these and some blooms

THE WATER-SIDE ROCKERY AT SEDGEMERE, MARKET BOSWORTH.

several fine blooms, auguring well for the show they will make in another year or two.

The other illustration gives us a glimpse of one of the farther reaches of the rockery with a corner of the larger pond in the foreground. A pathway along the back of the rockery leads into an overhung walk between the trees, and hereabouts are massive clumps of *Cimicifugas*, *Polygonatum*s and fine hardy Ferns. Farther on beyond the second pool is another great drift of *Astilbes* and *Spiræas* and as fine a colony of the scarce *Montbretia rosea* as I have ever seen. In spring the grassy drifts along the winding paths are bestrewn with Daffodils, Scillas, Anemones, and crowds of Primroses and Forget-me-nots, and in winter there will be bright berries on many

greater expense and labour have endeavoured to remodel and reconstruct the whole place, introducing features foreign to their surroundings and endeavouring to grow kinds that would require constant nursing and irksome attention. As it is, he has an extraordinary collection of charming and delightful plants, the majority of which are now as firmly established as in their natural homes and as capable of taking care of themselves as the very Grasses and Rushes and trees that grew there during the period of neglect and desertion. How many places in this land of ours might be similarly and as successfully treated? It is a question of the development of a garden in contrast to the mere making of one.

A. J. MACSELF.

CORRESPONDENCE

THE "GENTIANELLA" AND OTHER GENTIANS.

MR. INGWERSEN'S article (page 501) is interesting and ingenious, and the cultural part of it most useful. I agree with him in not accepting the name of *Gentiana Gentianella* for the old favourite of our gardens. And I agree with you, sir, that we cannot revert to the name *acaulis*, which is dropped by modern botanists; but I doubt if *G. excisa* var. *Gentianella* is the name to be adopted. In my "Alpine Plants of Europe," 1911, I said of *G. excisa*: "This Bell-Gentian is the one which is generally called in England *G. acaulis*, and too frequently goes under the absurd diminutive title of *Gentianella* in books on gardening." I did not then know that *Gentianella* was the name which Moench gave to the genus which Tournefort (1656-1708), and afterwards Linné, called *Gentiana*. But in *Irish Gardening*, March, 1918, M. Correvon,

in writing on the *acaulis* group, said: "Lastly, there is the most brilliant of all, *G. angustifolia*, of the Alps of Dauphiné, which under the name of *Gentianella* has been grown in English gardens for 300 years." He then described it. In THE GARDEN, March 11, 1922, page 113, M. Correvon had an article on "The Adaptation of Plants to Environment, Illustrated by the *Gentianella* and its Alpine Cousins." There he says "The old *Gentianella* of English gardens was introduced into England at the end of the sixteenth century. Its characteristics differ from those of the wild type, having been adapted to the mild climate." He brought some with him from England and cultivated them forty years ago near other types to study their adaptation. This began at the Linnaea garden at 5,800ft. altitude in Valais, and was continued at Floraire, near Geneva. With the "*Gentianella*" he grew all the different *acaulis*-forms (*angustifolia*, *alpina*, *Clusii*, *dinaria* and

of the tall and stately yellow Cone-flower—*Rudbeckia grandiflora* (single) or *R. californica*—as I was gathering flowers for the house gave me an idea. I used the Aster as a sort of carpet plant through which came the taller stems of the Cone-flowers, bearing their quaint "lop-eared" petals round the small sugar-loaf-shaped tall centres. I think it was a distinct hit from remarks that have been passed upon it. Any tall, long-stemmed yellow might be substituted for the *Rudbeckia*. I have since tried *Coreopsis grandiflora* and it was presentable, but far from equalling the arrangement described. The long, hanging, lop-eared petals and its upright, stiff stems were undoubtedly the secret of *Rudbeckia*'s success and, remembering the big dog in the picture, they suggested the heading of this note.

As I write I have an odd plant or two of *Aster ptarmicoides* in bloom and I am wishing I had some of the purple *Rudbeckia* (purpurea) to play dignity to the little, unpretentious white Aster. It would not be a bad combination. Is there a lop-eared white flower that would go with it?—JOSEPH JACOB.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Potatoes.—The lifting of Potatoes should be completed and the tubers stored in a frost-proof shed. Cover the tubers with a layer of straw to keep out the light, or the top layer will become green and unfit for consumption. To save further trouble they should be graded into three sections—ware, seed and small. The last-named may be disposed of at once and the seed tubers placed in a separate heap to be dealt with later when an opportunity occurs.

Carrots that are ready may be lifted and stored in sand or ashes, choosing as cool a place as possible. Beet and Turnips may be dealt with in a similar way.

Asparagus-Beds.—When the season's growth has ripened it should be cut off, collected and burnt, the ground cleared of any weeds, and the surface pricked over lightly with a fork, taking care not to injure the crowns. A thin layer of manure may be afforded and allowed to remain throughout the winter. The spaces between the beds may be dug over, and everything made clean and tidy.

Cabbages.—Plantations already established should be kept free from weeds and hoed occasionally when the surface is sufficiently dry for the purpose. Any failures in the rows should be replaced, and a few more lines may be planted for succession. If we experience a hard winter, this crop may prove the most valuable.

Cauliflowers should be examined frequently and those in a forward state may have the top leaves bent over, which will be sufficient to protect them from a few degrees of frost. If there is a glut, the plants may be lifted and hung head downwards in a cool shed, or the roots may be laid in ashes or sand.

The Flower Garden.

Lifting Plants.—In some gardens specimen plants of *Heliotrope*, *Pelargonium*, *Fuchsia*, etc., are employed in the summer bedding schemes, and where such is the case it is not advisable to leave them in the open very long after this date. When they are lifted they should be potted up and placed in the greenhouse, and if the weather is bright the plants may be syringed overhead until they are re-established. Keep the house more or less closed for a few days, afterwards admitting plenty of air when outside conditions are favourable.

Begonias have been exceptionally good this season, but now they should be lifted and placed in shallow boxes to dry out. When at rest store in a frost-proof place and keep the tubers quite dry. It is advisable to examine them occasionally, and any showing signs of decay should be removed.

The Flower-Beds. During the next few weeks the beds should be cleared of their summer occupants and, after being given a liberal dressing

HYPERICUM CHINENSE.

ONE of the most pleasing shrubs in the garden at the present time is *Hypericum chinense*. I think it is much preferable to *H. patulum* Henryi, though the latter has this advantage, that it seeds itself freely and seems to come true. It is the only *Hypericum* I have which does so. Of the two, however, I think *H. p. Henryi* is the hardier, as I do not recollect it ever having been cut to the ground by frost, while others like *H. Moserianum* frequently suffer thus. A charming autumn effect can be obtained by a wall clad with *Rhus Toxicodendron* (Poison Ivy) and in the foreground large clumps of *Anemone japonica alba* and *H. chinense*, all of which will be making their most brilliant efforts at the same time and last for several weeks. While, if the border be planted with *Lilium regale*, the early summer effect will be charming, and the dead stems of the *Anemone* and branches of the *Hypericum* will ward off spring frosts, which are so fatal to many Lilies, and their stems in turn will have withered up ere the autumn blaze, as suggested, commences.—FORMAKIN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Storing Roots.—The following root crops should now be carefully lifted and stored in the root cellar either in sifted ashes or sand: Carrots, Turnips—both ordinary and Swedes—Salsify and Scorzoneria. Take special care not to break the roots of either of the two last named. Parsnips, like Jerusalem Artichokes, are best left in the ground and only lifted as required for use.

Hoeing.—The hoeing season is now about over, but a final hoeing should be given on a fine dry day to such crops as Leeks, Spring Cabbage, Spinach, Onions and Parsley. This will keep any seedling weeds in check and will make the surface soil sweet and fresh.

Asparagus.—As soon as the "grass" has matured, cut the stems over about 3 ins. above the ground, rid the beds of weeds, lightly fork the soil between the rows in the beds and give a mulching of good farmyard manure about 3 ins. in depth. Finish off by forking a little more deeply in the alleys and apply a light mulch along them too, as the roots travel into them on either side. The decayed stems will prove valuable for protecting plants of doubtful hardiness during severe weather.

Fruits Under Glass.

Peaches that are to be started early should be pruned without delay. The fruit-bearing shoot of the past season should be cut away close to the succession shoot which now takes its place. Cut away in. or 2 ins. of the immature wood at the tip of the succession shoot, making sure that the cut is made immediately beyond a wood bud. The wood buds are easily distinguished from the fruit buds, being more elongated. The general framework of the tree should, of course, be maintained, therefore any dead or diseased branches should be cut away and young wood encouraged to take their places.

The Flower Garden.

Spring Bedding.—This work should be carried through without delay. Owing to the comparatively high price of bulbs nowadays, greater use is being made of the humble Wall-flower, and, since there is such variety of colour available, wonderful effects can be produced with them. The following varieties are all quite distinct: Vulcan, Fire King, Orange Bedder, Golden Monarch, Primrose Dame, Eastern Queen and Ruby Gem. This does not complete the list, although some of the varieties offered by different firms differ only in name. The Forget-me-not and the Daisy, too, may be utilised with good effect. Among bulbous plants for this particular work, reliance should be placed mainly on the early Tulips, as they finish off in time to admit of the summer bedding being carried through in season.

Bulb Planting.—This will demand chief attention in the mixed flower garden for the next week or two. Tulips, Cottage and Darwin varieties, are the most valuable for large effects. Daffodils, too, are suitable for massing, and are often at their best in grass or in the wild garden. For early summer display, Irises, both English and Spanish, are invaluable. Among miscellaneous bulbs the following are all worthy of inclusion: Snowdrops, Chionodoxas, Scillas, Grape Hyacinths, Iris reticulata, Dog's Tooth Violets (*Erythroniums*), Crocuses, Camassias and many others. Clumps of three or more are always more effective than single specimens.

Liliums are too important a genus to be included among miscellaneous bulbs. Here one can only indicate a few species which may, and should be, grown by all and sundry. *Lilium croceum* (the Orange Lily) is an everyman's flower as is also *L. tigrinum* (Tiger Lily) with improved varieties. *Lilium candidum* (Madonna Lily), of purest white and richly fragrant, should be in every garden—plant early. *L. testaceum* (Nankeen Lily) is easily grown and is very floriferous with an uncommon shade of colour, as its garden name suggests. *L. pardalinum*, with its purple-spotted orange red flowers, is another good doer when given somewhat moist conditions. I close this restricted list with that brightest of all the Lilies, *L. chalcedonicum*, the Scarlet Turk's Cap Lily. It is not quite such a sure doer as the others I have mentioned, but could not be fairly called fastidious in its requirements. If the bulbs are surrounded with a little sharp sand it will help to ensure success.

GREENHOUSE AND CONSERVATORY.

Storing Plants for the Winter. Large specimen Hydrangeas may be stored in a frost proof shed if a greenhouse space is available. They should be kept dry all the winter, although care should be taken that they do not get too dry. Thus it may be necessary to water them once or twice during the winter.

Fuchsias. Large specimen plants from which water has been gradually withheld should be wintered in the same way as Hydrangeas, while younger plants are best wintered under moister conditions. A frame from which frost can be excluded suits them very well. Standing on the ground they should get sufficient moisture to keep them from drying up too much. Young plants that have little or no hard wood frequently die if allowed to get too dry. Young Fuchsias rooted last month should be kept growing steadily on all through the winter.

Cannas, Crinum, Eucomis, Agapanthus and such-like plants may all be safely stored for the winter in a fairly dry shed from which frost can be excluded. Cannas may be turned out of their pots and stored with the balls of soil intact, as this prevents them from drying out too much. If kept too dry they seem to suffer and do not start well the following season.

Primulas. Many of the hardy Primulas, such as *P. denticulata*, *japonica*, *Bulleyana*, *Beesiana* and *pulverulenta* are excellent for the cool greenhouse. The best plants are obtained by planting them out for the growing season. Where this has been done the plants should now be lifted and placed in suitable-sized pots. If they are large well grown plants, 6 in. or 7 in. pots will be necessary. After potting, they should be stood in cold frames. As all the Primulas mentioned are really hardy, they are very useful for the small unheated greenhouse. They are all easily raised from seed, and strong stock may be maintained by raising a batch each year from seed.

Wallflowers.—The double varieties, of which there are tall and dwarf strains, are very useful for furnishing the greenhouse and conservatory. Plants that have been grown for this purpose should now be lifted and potted up. They should be potted fairly firm, and have some lime or old mortar rubble added to the potting compost. After potting, they should be stood in cold frames, giving them plenty of air on all favourable occasions.

Canterbury Bells.—Well grown plants are very fine for conservatory decoration, and the plants should now be lifted and placed in suitable-sized pots. If good examples are to be grown, 8 in. or 9 in. pots are necessary. They may be stood outdoors at the foot of a wall if a cold frame is not available. Although quite hardy, they often suffer from damp, and in this respect they prove very troublesome in the neighbourhood of London.

Achusa italica Dropmore var.—Although not generally used for greenhouse decoration, this plant is excellent for the purpose. If grown on in a cool house they flower several weeks in advance of the outdoor plants and last in flower for quite a long time. The varieties *Opal* and *Pride of Dover* are equally suitable for this purpose. Three strong crowns may be placed in an 8-in. pot, plunging them to the rim in ashes outdoors until such time as it is necessary to take them indoors.

Caryopteris Mastacanthus is hardy in the South in dry, warm situations. This pretty plant, which is now in flower in the colder parts of the country, is well worth growing for the cool greenhouse. It is naturally of a neat bushy habit, and its greyish foliage and violet blue flowers are very pretty. It is easily propagated by means of cuttings, especially if a stock plant is taken indoors during the spring. The newer *Caryopteris tauguetia*, which is a slenderer and more lax growing plant with deeper coloured flowers, promises to be equally useful for the cool greenhouse.

Cinerarias. The later-sown batch of plants should be ready for their flowering pots. They enjoy cool, moist conditions, and should now be placed in low pits, keeping them well up to the root glass. No more fire-heat need be given than is necessary to exclude frost. The earlier batches that have well filled their pots with roots should now be given frequent applications of diluted liquid manure and soot water. These plants are very subject to attacks by green fly, which may be prevented by frequent light fumigations.

Royal Botanic Gardens, Kew.

J. COURTS.

The Swamp Blueberry. *Vaccinium corymbosum* is perhaps the best known of the American *Vaccinums* in our gardens, and is probably the most worthy of culture. Though commonly known as the Swamp Blueberry, it will prosper in any cool loam that does not get too dry in summer, but peat (or leaf-mould) is more to its liking. *V. corymbosum* is usually seen as a medium-sized shrub with rigid, branching stems which have a tendency to arch at the tips. It varies a good deal, however, in habit, and the pale green leaves may be narrow and willow-like or considerably more ovate. In most forms these are slightly hairy, especially when young, and before falling in autumn they assume really fine tints. The flowers, which appear in clusters in the late spring on the previous year's wood, are nearly $\frac{1}{2}$ in. long, cylindrical, slightly contracted at the mouth and of a pale bluish colour. These are followed by black berries and willow-like size of Currants and covered with a bluish bloom. In flavour they are somewhat like our common Bilberry (*V. Myrtillus*).

The Judas Tree.—Of the small genus *Cercis*, this species (*C. Siliquastrum*) is the most familiar, though it is by no means common in gardens. It is one of the oldest of exotic trees, having been introduced to this country from Southern Europe in 1590. The generic name appears to have been bestowed upon it by Theophrastus some two hundred years before the Christian Era, and tradition has it that it was upon a tree of this kind that Judas hanged himself. *C. Siliquastrum* is generally seen as a low, somewhat spreading tree of 15 ft. to 20 ft. in height, but it will attain a much greater height. It is a deciduous species, the broad, rounded leaves being a pale green changing to yellow in autumn. The flowers, which appear before the leaves in spring, are pea-shaped and are produced at the joints of the old wood, or even from the trunk. They vary a good deal in colour, but in average specimens they are a full toned rosy lilac, so that a Judas Tree laden with these pretty blossoms on a sunny day in May is a very beautiful object. There is a variety with white flowers. Much of the beauty of the Judas Tree, however, lies in its

characteristic habit of growth and equally remarkable bark. *C. Siliquastrum* is naturally a sun-lover, and it will thrive in any well drained loam, the situation being one that is sheltered from cold spring winds and late frosts.

Eucryphia pinnatifolia.—Though this exceedingly attractive plant was introduced from Chile in 1850, it is still uncommon in gardens. This is probably due to difficulties in propagation, to its objection to root disturbance and to frequent losses among young plants. It is, however, quite hardy enough for all but our bleaker localities, and when once established it is a free and contented doer in any cool, lime-free loam or peaty soil in which Heaths do well. *E. pinnatifolia* is usually seen as a tall bush, or small tree, up to 10 ft. or so in height. It is a deciduous species, or practically so, and bears its leaves, which are somewhat like those of a Rose, in clusters at the ends of its rather stiff, upright shoots. The beautiful flowers (2 in. to 3 in. across), which are produced in the later summer, consist of four broad, creamy-white petals with a bold cluster of numerous yellow-anthered stamens at the centre. The foliage becomes a brilliant orange in autumn.

An Autumn-flowering Arabis.—The rose-pink *Arabis Sundermanni*, though it blooms in spring as freely as the common white one, deserves some consideration as an autumn-flowerer. For not only is its colour good—probably better than that of any of the other pink members of the species—but the habit is neat, and vigorous young plants, cut back in summer, will often be a mass of blossoms during September and later. *A. Sundermanni* does best in a fairly cool soil with shade from the mid-day sun and enjoys an annual dressing of old manure with some broken mortar.

FORTHCOMING EVENTS.

October 16.—Royal Horticultural Society's Fortnightly Meeting.—Winchester Horticultural Society's Meeting.

NAMES OF PLANTS.—Mrs. S. J. Glos.—*Linaria purpurea*.—C. M. W.—*Minulus (Diplacus) glutinosus*.—H. B. (Limp-field).—1, *Erica cinerea*; 2, *E. vagans*; 3, *E. carnea*; 4, *Fuchsia macrostemma* var. *gracilis*; 5, *F. m.* var. *Riccartoni*; 6, *Lonicera flexuosa*.

NEW SPRAYING MACHINES LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete without a Sprayer, in fact a Sprayer is absolutely essential to obtain best results. During the War we supplied a considerable number of our well known Four Oaks Knapsack Sprayers—Rubber Diaphragm type—to the Government, and we have just re-purchased a small quantity back again, which have never been used. They are made of copper but painted Service grey colour. They have various special additions to the ordinary machines, and the price to-day would be £5 each. We guarantee them to be in perfect working order as new. We will send one machine carefully packed, carriage paid, on receipt of 50/-, but cash must accompany all orders. We would supply 2 machines for 90/-, carriage paid.

Please mention this Paper when ordering.

VIOLETS AND CARNATIONS, fine plants, from 3/6 & 4/6 doz. List.—**WHITE, c/o COLINTON, Ross-on-Wye.**

STRIKING NEW PERENNIAL VERBASCUMS. "Cotswold Queen"—Very beautiful crushed strawberry, each 5/-; "Cotswold Beauty"—Deep biscuit, shaded purple, each 3/6; "Cotswold Gem"—Light bronzy yellow, purple shadings, each 3/6.

DOUBLE WHITE ROCKET (Hesperis Matronalis Alba Plena), extra fine stock of this sweet-smelling favourite. Strong plants, 3 for 2/6, 12 for 9/-, 100 for 55/-, carriage paid for cash with order.—**R. TUCKER & SONS,** Brookside Nurseries, Headington, Oxford.

RARE ALPINE & ROCK PLANTS, a few selected from our enormous collection:—*Androsace pyrenaica*, 1/6; *Anemone Vernalis*, 1/-; *Dianthus alpinus* and *albus*, 1/-; *Iris gracillipes*, 1/6; *Saxifraga Burseriana sulphurea*, 1/6; *Campanula pseudo-Raineri*, 1/-; *C. Miranda*, 1/-; *Aethionema pulchellum*, 1/-; *Arenaria balcanica*, 6d.—**R. TUCKER & SONS.**

LISSADELL.—A few really good Rock Garden Plants:—*Campanula W. H. Palse*, *Dianthus cæsius grandiflorus*, *D. neglectus*, *Gypsophylla frutescens*, *Hypericum reptans*, *Iberis saxatilis*, *Phlox Vivid*, *Saxifraga lantoscana* Lissadell, *S. longifolia*, *Viola gracilis*, all 9d. each; postage extra. One each of the lot for 7/6, post free. Cash with order.—**MANAOFB, Lissadell, Sligo.**

BIRDS' BATHS, GARDEN VASES, SUN-DIALS, NESTING BOXES. Catalogue (No. 4) free.—**MOORTON, 60, Buckingham Palace Road, S.W.**

SWEET PEAS AND HOW TO EXCEL WITH THEM. By HORACE WRIGHT, 9d. net, by post 11d. Published at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

DOWNER'S NEW LUPINS. Giant Stride in Evolution. Marvellous colours. 60 seeds, 5/-.—**DOWNER** (Dept. 2), Drayton Manor Nurseries, Chichester.

BARR'S GOLD MEDAL DAFFODILS.

The finest sorts for Pots, Bowls, Exhibition, Flower Borders and to Naturalise. Also many New Seedling Varieties, offered for the first time. Descriptive Catalogue free.

BARR'S HYACINTHS, TULIPS, LILIES, CROCUSES, IRISES, etc., for pots and bedding. Finest quality. Descriptive Catalogue, with special directions for the culture of Bulbs in Bowls, free.—**BARR AND SONS, 11, 12 and 13, King Street, Covent Garden, London, W.C.2.**

THE DOUGLAS CLOVES.—Our wonderful new strain of Hardy Border Clove Carnations again won the Large Silver Cup at the R.H.S. at the Great Chelsea Show, June, 1923. We have now won more Awards of Merit of Royal Horticultural Society for Carnations than any other two firms together. Rigid stems, perfect calyx, glorious scent. New plant list.—**DOUGLAS, Edenside, Bookham.**

Notes from Maidstone.

CHERRIES.

It is not generally recognised that the colder garden walls will grow the Sweet Cherries as well as the universal Morello. We should recommend Governor Wood, Bigarreus Kentish and Napoleon, and in the Black Cherries, Early Rivers, Schrecken Bigarreus, Waterloo and Tradescant's Heart, a selection which covers the whole range of the Cherry season. We can supply good Fan Trained Trees of these at 15/- each, or smaller at 10/6.

Established 1796.

The Royal Nurseries,
Maidstone.

Do YOU know PARSONS

WORCESTER BERRY?

If not, you have yet to learn of one of the most useful berries in cultivation;

and WHY?

It has **proved its worth** as a decided marvel in berry-bearing fruits, viz.:

As a Cropper.

As a Jam or Jelly Fruit, or for Tarts.

As a resister of Big Bud (or Mite) and Mildew.

Owing to heavy demands I have only a limited quantity, but offer, as far as my stock will permit, as follows:

Bushes or Single Cordons ..	2 6 to 3/- each
Extra Strong Fruiting Bushes..	3 6 to 5/- each
Double and Treble Cordons or Fan Trained, for Walls, Trellis, etc., Extra Strong Fruiting ..	3 6 to 5/- each

Packing and Postage extra, viz.:

1 plant, 9d.; 2 do., 1/-; 3 do., 1 3/4; 4 do., 1 6/8; 6 or more, carriage paid.

It has attracted enormous attention when exhibited at Shrewsbury, Harrogate, Glasgow and Edinburgh Shows, and the opinion of some hundreds who tasted it was "a delicious fruit."

If you have not seen above, ask for a copy of my New Fruit List FREE, with Coloured Plate of my Berry, Press Extracts, and Testimonials.

My List includes ALL THE BEST in APPLES, PEARS, PLUMS, etc., and my Worcester Grown FIBROUS-ROOTED Trees may be relied upon for BEST RESULTS and QUICK RETURNS.

[OCTOBER 20, 1923.]

ALPINES AND THEIR CULTURE

ALPINE plants and other choice species and varieties suitable for the rock garden are supplied almost entirely from pots, so that they may be put into their permanent positions at practically any season. It is not wise, however, to choose the middle of a summer drought or the dead of winter for the operation. Winter will soon be upon us, and a few words about alpine culture may not be inappropriate before planting closes down for the season.

Rock gardens of some extent are common, but the number of such which contain a really good collection of kinds is not so great as it might be. In some cases the idea, originally, was to grow large masses of a few effective sorts of which the culture is of the easiest. An understandable viewpoint this, but outside our purview at the moment! The greater number, however, had originally a wide range of plants of varying degrees of choiceness, and the apparently healthy rock garden is, in fact, little better than a graveyard, overgrown with weeds. Very often the choicest kinds are found in quite small rock gardens, or even on the rockery bank of the suburban garden.

Why is this? One rather obvious reason is that when laying out a rock garden many people "bite off more than they can chew," for, in the nature of things, rockery is not inexpensive to maintain, the weeding alone being a very considerable item. Then, again, if the choice species are dotted about almost indiscriminately over the whole garden, this in itself increases the work several-fold, because the same close attention must be paid to the whole garden, which

otherwise would suffice for a comparatively small part. If this attention is not afforded, the stronger, coarser-growing kinds quickly smother the smaller and choicer ones.

Thin planting is a common explanation of failure, or comparative failure, with trees and shrubs in the present-day garden; with choice alpine plants it is an even commoner cause of non-success. Plants which, in their native mountains, form part of a close alpine turf can hardly be expected to luxuriate under very dissimilar climatic conditions when isolated. Their roots under such circumstances are alternately parched and water-logged, frost and thaw loosen the hold of the plant upon the soil and a valuable plant has become a casualty.

The introduction of fine Grasses from the alpine lawns has often been tried, but never with any measure of success. It is difficult to provide them, in our lowland gardens, with conditions under which they will thrive, more difficult to prevent them from losing character, and all but impossible to distinguish them clearly from the

grass weeds which spring up and choke one's choicest plants.

Many plants may be grown in the "moraine" which are not in nature moraine plants, because the finely broken stone retains moisture well, provides a cool root-run for the plants, and even modifies to some extent the atmosphere above it for a few inches, greatly to the advantage of the little plants. The moraine, however, seems inadequate for certain stoloniferous plants such as *Gentiana verna*, which is difficult to flower satisfactorily in our drier countries. For these Mr. Clarence Elliott's notion of an alpine "turf" composed entirely of small-growing alpine plants should prove invaluable, though it may be that there is some reason for *Gentiana verna* (and the *Gentianella* for that matter) not flowering, apart from climatic conditions. However that may be, Mr. Elliott's stone pans (pig-troughs to be exact) absolutely crowded with vegetation were the object-lesson of the 1923 Chelsea Show. The "alpine lawn" idea, however, cannot

altogether supersede the moraine; these two adjuncts to the rock garden must be considered complementary rather than antagonistic.

Many people are chary of putting down a moraine because they have seen some which were, to quote a keen lady gardener, "abominably ugly excrescences." Admittedly, a "moraine" can easily be ugly, but in fact it need neither be unsightly nor an excrescence. Indeed, very often the moraine gives a diversity of appearance to the rock garden which is very desirable. Cause the rock garden cliffs to fall back, leaving a little valley not so wide as to be disproportionate to the rock garden as a

A BEAUTIFUL YELLOW-FLOWERED KABSCHIA SAXIFRAGE, GROWN BY MESSRS. TUCKER OF OXFORD AS *S. SARTORII*, WHICH SHOULD SUPERSEDE *S. APICULATA*.

and the plants are not so much as the stepping-stones in the path. A few plants are so small that they can be buried in the soil, and the more the better.

The best spot for the moraine is a westerly or cool the same aspect is very desirable for many plants, which do not require a moraine or a deep, and special treatment. Such an exposure gives shelter from parching easterly winds, while allowing the generally moisture-laden winds from the west, south west and north-west ready access. It prevents in springtime the morning sun from scorching frozen blossoms, and it is less trying in the heat of summer to the majority of alpine plants than a bank with a southerly aspect.

Some will like the cliff, others a flat, not over-dry ledge, but all the Saxifrages ordinarily grown in rock gardens like the western slope. The Encrusted forms have a preference for a fairly sunny place, and the "Mosses" for one where too much direct sunlight does not penetrate, the Kabschias falling in between in their requirements; but a representative collection of *Funaria*, *Kabschia* and *Dactyloides* Saxifrages could be grown very successfully on a stone-lined bank sloping down from east to west.

If planted on a bank, a similar exposure suits the Gentians, but many of the larger growers succeed quite well in a cool, rather stony cool on the flat. This is the case with *G. septemloba* and *Phacelia* and their various forms with the *Gentiana*, and with some of the newer Asiatic species, including *G. sinensis* and *Farrerii*. In most localities even *G. verna* respond well to similar treatment.

We will not waste space by lingering over the effective and space filling, but by no means choice, *Aubrietias*, *subulata* *Phloxes*, *Aralis* and *Iberis* species and such-like. Let it suffice to mention that a westerly exposure is ideal for the lot of them.

With *Primula* and *Androsace* we are back among the gardener's favourites. Most of the *Primula* of the *Auricula* class like an open, fairly sunny position, some of them, indeed, are not averse to regular sun baths in summer-time, but, for them for all in all, a westerly aspect suits them. Most of the *Candelabra* section like moist, not to say boggy, conditions and not too much direct sunlight; the same may be said of *P. rosea*. Beyond these there are *Primulas* of many sorts, those of the *capitata* set, for instance, those which gardeners think would have been best left under the name of *Onophthalma* (typified by *P. vinciflora* and *Viola grandis*), those which seem to mimic the *Field Orchis* (including such as *P. Giraldiana* and *Littoriana*), a small host of forms more or less closely related to *P. cortusoides*, the relatives and forms of *P. farinosa* and those of *P. sibirica*, some species which closely approach *Androsace*, and a number which can hardly be classed with any of the foregoing. Some of the newest introductions are, to put it mildly, doubtfully winter-hard, but when the time comes to try any of them outdoors consult Farrer, if you wish for compacts; but, unless the appearance of the plant gives strong grounds for thinking it can be put in a cool but well drained corner with a north-westerly aspect.

The *Androsace*, on the other hand, like an open sunny position, though one not too sun-baked. The *Androsace* of the *Androsace* class, such as *A. cuneata* and *A. lactea*, should, however, be put in a sunny position as much as possible, while *A. cuneata* and *A. lactea* should be put in a sunny position as much as possible. The *Androsace* of the *Androsace* class, such as *A. cuneata* and *A. lactea*, should, however, be put in a sunny position as much as possible. The *Androsace* of the *Androsace* class, such as *A. cuneata* and *A. lactea*, should, however, be put in a sunny position as much as possible.

A TYPICAL OMPHALGRAMMA PRIMULA, THE VIOLET-COLOURED *P. VINCEFLORA*.

THE WHITE-FLOWERED *DRABA DEDEANA*, A CHOICE PLANT FOR THE MORaine.

ANOTHER MORaine PLANT—A SUN-LOVER—*Silene hookeri*, WITH CLEAR PINK BLOSSOMS.

place often turn red, but this seems to be a measure of protection rather than a sign of ill-health, for such plants usually increase well and flower profusely. *A. carnea*, of course, is a peat-loving species; no consideration of the best aspect for it must obscure that. Many gardeners plant the silky-foliaged forms on an eastern slope as less exposed to driving rains and splashing, but practice does not, in this instance, bear out theory, so that a western or south-western aspect seems to suit almost all the species, including the admittedly difficult *Aretia* forms typified by *A. helvetica*. This plant is most likely to succeed wedged firmly between fair-sized pieces of rock in the limestone moraine.

Sedum (with a few notable exceptions) and *Sempervivum* need no special accommodation,

but like all the sunlight that is going, and the same may be said of the Sun Roses (*Helianthemum*) and their bigger cousins the true Rock Roses (*Cistus*). Hardy Cacti and *Mesembryanthemums* (where they stand the winter outdoors) naturally like a scorching corner, but it would not be easy to mention many more which prefer full sunlight to a site where the noon sun, if it comes, only strikes along the rock, not full upon it. Another week we may touch upon the plants which like a northerly aspect—more than one might expect—but for the moment we will simply make the point that positions which face more or less to the west are the most generally desirable. If one must grow one's alpine on a rockery bank—as many a gardener is forced to do—one is lucky (other things being equal) if the bank faces west.

Mr. E. H. Wilson, who first sent home seeds in 1900 or 1901. He describes it as a large bush or small tree up to 30 ft. high. On vigorous young plants the largest leaves exceed 1 ft. in length and are 1 ins. to 5 ins. broad. We had a shock when the plants first shed the oldest leaves in July, but this has since proved to be an annual occurrence. The large funnel-shaped flowers are pink tinted when they first open, fading to white with age. In a wild state there is said to be a good pink form, but I have not heard of this flowering under cultivation. *R. auriculatum* is proving to be a very good seed-bearing parent, having been pollinated with numbers of hybrids and several species in different gardens where it has flowered. The species is also being extensively raised from home-saved seeds. The propagator in one large nursery recently informed me that they had 5,000 seedling plants.

R. BRACHYCARPUM is a Japanese species flowering in June and July. It has creamy white flowers, flushed with pink and yellow. The plants form sturdy and compact evergreen bushes, not perhaps in the first flight as showy flowering shrubs, but possessing desirable characters for breeding purposes.

R. DECORUM in its many forms flowers from May to July. Mr. Wilson describes it as one of the most widely distributed Chinese *Rhododendrons*. Hence it is not surprising to find a very considerable difference in the foliage and colour of the flowers, which vary from white to rich pink. The blossoms have a very pleasing fragrance.

R. DISCOLOR may prove even a better parent

THE LATER-FLOWERING EVERGREEN RHODODENDRONS

The introduction of several large-leaved evergreen Rhododendrons from China, flowering in late summer, offers wide possibilities to the hybridist.

THE great majority of large-leaved evergreen *Rhododendrons* flower during April, May and early June. The introduction from China of *R. discolor*, flowering in July, the August-blooming *R. auriculatum*, and *R. serotinum*, which has many open flower-trusses in August, September and even October, offers wide possibilities of a summer-flowering race of evergreen *Rhododendrons*. These, with *R. maximum* from the United States and the Japanese *R. brachycarpum*, should prove good seed-bearing and pollen parents, all being perfectly hardy and of easy culture.

As most of these have white or light-coloured flowers, the particularly valuable hybrids to pollinate with them will be those with richly coloured blossoms. Some of the later May and June flowering sorts which should be useful include Lord Roberts, rosy scarlet; Doncaster, rich red; The Warrior, rosy purple; John Waterer, dark crimson; C. S. Sargent, dark red; John Spencer, rose with pink markings; and Charles Noble, rosy red, yellow markings. The pure white variety Snowflake is one of the best June-flowering hybrid *Rhododendrons*. In view of its free-flowering and bushy habit this should be useful to pollinate with *R. auriculatum* and *R. discolor* in particular.

Various methods can be adopted to bring the plants into flower at the same time. Introducing the late-blooming species into a greenhouse and advancing the flowering a month or six weeks has been done with success. The flowering season of Doncaster, Charles Noble and other hybrids can be retarded by moving the plants to a north position where a high wall makes the position cool, moist and shaded from all the sunlight. It is also possible to keep pollen for several weeks in good condition in small glass phials.

There is always the chance of picking up pollen from a precocious flower here and there, especially when a considerable amount of transplanting is done each winter. One of the most interesting crosses made at Kew among these *Rhododendrons* was the crossing of *R. auriculatum* with pollen from precocious flowers of *R. ponticum*. There is very distinct evidence of both parents in the foliage of the seedlings, none of which has yet flowered.

In crossing *Rhododendrons* it is found in practice that, with few exceptions, the best results are obtained when one of the parents, preferably the seed-bearer, is a species. In using a species there

is a definite fixed base to work upon, which is very desirable when there is a definite objective in making a cross. When hybrids of named varieties only are used in crossing, the result is, at best, very uncertain.

R. AURICULATUM.—In some respects this is the most distinct and valuable species introduced

A GOOD SPECIMEN OF RHODODENDRON AURICULATUM.

during recent years from China. With us the flowering season is August. Under varying conditions in different gardens we hear of plants flowering from July to September or October. It is also very late starting into growth, for it is not until July that the young shoots commence to develop. This species is a native of Hupeh, by no means common in a wild state, says

than *R. auriculatum* in the breeding of a race of summer-flowering *Rhododendrons*. Though not so strikingly distinct, *R. discolor* makes a better branched evergreen bush and is more free-flowering. The colour of the large funnel-shaped blooms, the largest of which approach 6 ins. across, vary from white to deep glowing pink. July is the flowering season.

A FINE PLANT OF RHODODENDRON MAXIMUM.

R. MAXIMUM, the great Laurel or Rose Bay of the United States, was first introduced to British gardens in 1730. It is not a particularly showy flowering shrub, as the flower-trusses open in late June or July when the young growths are well advanced. The colour of the flowers is pale pink, or rose, spotted and flushed with yellow. There is also a white variety. *R. maximum* has not up to now been very extensively used for breeding, but crossed with the large up-standing flowers of *R. discolor* or *R. auriculatum* we might get something good.

R. SCROTINUM when first introduced from the Jardin des Plantes, Paris, in 1880, received the name and was grown for some years as *R. decorum*. From that species, however, it differs, among other characters, in having thinner and longer branches, forming a rather straggly bush. Its chief value lies in the flowering season, which extends from July to October. The white flowers are pleasantly fragrant.

SHUTTER.

In selecting positions for planting Rhododendrons which flower in summer, the most important consideration is shade from the fierce rays of the sun. Growing in the open, the flowers cannot last long in strong summer sunlight. Moisture at the roots is equally important; here, again, shelter seems called for, coupled with very liberal mulching with decaying leaves, pieces of broken sticks and twigs which help to hold the leaves in position, blacken and perhaps a small quantity of old straw manure if the soil is light and sandy. Even the hardy hybrid Rhododendrons will not succeed indefinitely without occasional mulching.

A. O.

SOME GENTIANAS

THERE are some among the many flower names in existence that immediately suggest

great altitudes and romantic solitudes. Perhaps the most familiar of these is that of the Gentian, the flower of Gentius, King of Illyria. This family of plants has a special fascination for the rock gardener, and with a few well chosen species a succession of blooms may be obtained, which will continue from early spring until the beginning of winter. The first to appear are *Gentiana verna* and *G. bavarica*. The former is a native and may be found in Yorkshire and several parts of Ireland. Both varieties are difficult to grow, however, except in the moraine, and even there they prefer to have their roots running among other low-growing plants. Next in succession comes *G. acaulis* or *Gentianella*, an old favourite in many gardens, which blooms freely where the soil is suitable. When grown in strips of a foot or more wide, its large

blue blooms make a wonderful edging to a border. *G. asclepiadea* is another robust plant suitable either for the herbaceous border or the rock garden, as is also *G. septemfida*, which has flowers of a paler blue colour, and numerous hairs in the tube; these give a charming softness to its appearance. This last is easily grown in good soil, but is apt to suffer from transplantation. There is a very fine variety of *G. septemfida*, *Lagodechiana* by name, of which the flowers are hairless and of a

larger size and richer purple colouring than the type. The latest-flowering variety is *G. sinuata*, which blooms very freely in October and on into November. The flowers are dark blue inside and greenish-white outside, beautifully veined, with purple throughout. At this present moment there is a large patch of this variety, covered with buds, among the alpine in the Botanic Garden, Edinburgh, close to the most recently introduced and most lovely of all Gentians, called after its discoverer, *G. Farreri*.

A peculiar interest attaches to this flower which comes from the wild region, where Reginald Farrer found so many wonderful plants new to science, and where he ultimately lost his life. It was found by him in 1915, during one of his expeditions to Northern China, on the borders of Tibet. In his delightful book, "The Rainbow Bridge," he says, "This new Gentian instantly obliterates all others of its race, and sinks *Gentiana verna* and *Gentiana acaulis* into a common depth of dullness. . . ." One imagines him, a modern Linnaeus, kneeling in ecstasy before it. The history of its transference to these regions is in itself a little romance. The specimens Farrer collected were sent home to this country, but the trans-Siberian journey killed them all. Strange to say, however, by a fortunate accident, the seeds had already arrived in this country. The year before, when collecting the seed of another Gentian of a more common order, Farrer had observed that some of the pods which he had obtained were darker and thicker than the others. These were sent to the Edinburgh Botanic Garden for propagation and turned out to be seeds of *G. Farreri*, and these are the source of the present stock now blooming happily on this side of the world. The flower, about the size of the *G. acaulis*, is a little narrower in the tube. Farrer describes it as a "beautiful Cambridge blue with a white throat, and without there are long vandykes of periwinkle purple alternate with panels of nankeen, outlined in violet, with darker violet median lines." It is a free grower and can be increased by cuttings, but the best and hardest plants are obtained from seed. Some fine specimens are at present in bloom in the Edinburgh Botanic Garden. Others are growing in even greater profusion in Mr. Harley's garden at Glendevon, Perthshire, where the soil, the altitude and the most climate combine to bring all the Gentians to perfection. H. W. L.

THE BEAUTIFUL, BUT RATHER DIFFICULT GENTIANA BAVARICA.

ORNAMENTAL VINES

The value of the species and varieties of Vitis in gardens is chiefly due to the attractive foliage, which affords a wealth of rich autumn colour.

THERE is scope in most gardens for a freer use of hardy climbers. The vigorous climbing Roses, the Clematises and Vines, to name only three of the most important, add, wherever planted, a distinctive charm and beauty. The ornamental Vines in particular, when space permits of their luxuriant growth over arbours and trees, are distinctly suggestive of tropical or sub-tropical vegetation.

Somewhere in the neighbourhood of 400 species of *Vitis* have been described, but many of these are native of warm countries and quite unsuitable for outside culture in Britain. The *Vitis* collection at Kew, most of which is growing on the pergola near the Pagoda, comprises about fifty species and twenty-five varieties. For purely garden decoration it is easily possible to make a selection of twenty or twenty-five Vines possessing really considerable value for garden decoration. They have a special value for clothing bare walls and fences, climbing over outbuildings and summer-houses. Is there anything more beautiful than a wall festooned in autumn with the Virginian Creeper?

CULTIVATION.

Most species of *Vitis* can be readily increased by means of cuttings or "eyes" in close heated frames. The method is well known in connexion with the Grape Vine. Seeds and layering are alternative methods of increase when cuttings and "eyes" fail. The *Ampelopsis* section can be freely propagated by cuttings during late summer made of the half-ripe young shoots. Insert these in sandy soil in a propagating case with slight bottom heat.

The Ornamental Vines are moisture-loving plants. The soil should be deeply dug and manured before planting. Liberal mulching in summer, too, serves to provide the plants with food and to keep the soil cool and moist.

The proper pruning varies somewhat in the different species, but is largely a question of position. Where the space is unlimited, a little pruning will be desirable the first two or three years to form a framework; they can then be allowed to grow at will. The best results with the varieties of the Common Grape are obtained by hard spur-pruning, as is done with the fruiting sorts. A somewhat similar method of pruning can be adopted for the Common Virginian Creeper when used as a screen or curtain. Main rods are trained along the top, the shoots trail down in summer to be cut back each year before growths push again in spring.

PILLARS AND PERGOLAS.

In the open garden and pleasure grounds the ornamental Vines are cultivated in varying ways. A pergola can easily become a distinctive feature if suitably placed with some apparent objective, either over a path or a grass avenue. It may, lead, perhaps, from the rose garden to the pleasure grounds, or to the kitchen garden. Such a pergola should be at least 12ft. wide; for the vigorous-growing Vines 15ft. would be better, with the uprights on either side 10ft. to 12ft. apart.

Where a large Vine pergola is impracticable or undesirable, two or three arches spanning the walks in a small garden would effectively display the best of these climbing shrubs. My choice of three would be *VV. Coignetiae*, *vinifera* var. *purpurea*, and in a hot, sunny position, *heterophylla* var. *humulifolia*.

It is becoming a favourite practice to introduce here and there along the shrubbery and flower borders, wooden posts, or iron pillars, perhaps 10ft. to 12ft. or even 15ft. high, for climbing plants. The ornamental Vines comprise one of the most useful classes of plants for these positions. In preparing the wooden posts, or poles, short spurs 1ft. or more in length should be left when cutting off the side branches. This provides useful support for the long twining growths. If thin Larch poles are used, it is better to fix three

VITIS HETEROPHYLLA WITH STARTLING TURQUOISE BLUE BERRIES, BLACK SPOTTED.

of these tripod fashion. The tripod is also usually employed when iron supports, because of their lasting quality, are favoured.

While we value Vines in their varying degrees of vigour and variety of foliage for the porch, veranda, fence and wall, it is when we get out in the less severely kept parts of the garden or into the park and woodland among taller trees that the Vines can be used at least to imitate the luxuriant growth and beauty which travellers in the countries native to these plants are never tired of describing.

In selecting trees over which the Vines can ramble it is more a question of the position than planting against certain kinds of trees. Evergreen trees are perhaps preferable to display the gorgeous autumn colours of *V. Coignetiae*, for instance, but we also have this species a delightful sight

trailing through and over the branches of a stately Oak. The Evergreen Oak, Holly, Yew, Box and *Cryptomeria japonica* each and all provide suitable support and environment. Several of the tall Scotch Pines near the Kew Pagoda have the long trailing shoots of *V. quinquefolia* clothing the bare trunks to a height of 40ft. to 50ft.

It is desirable, may, one may even venture necessary, to prepare good stations for planting Vines to trail over trees if the best results are desired. The planting positions should, whenever possible, be on the outskirts of the branches. The Vine is a moisture-loving plant, and it will certainly not get very adequate supplies if planted beneath evergreen trees. Good stakes should be placed in position to support the growths for a few years after planting, so that they may take firm hold of the lower branches and not suffer damage from wind.

The hardy species we cultivate in gardens are mostly natives of North America, China and Japan. There is no British representative, and evidence suggests that even the Grape Vine, *V. vinifera*, was introduced to Europe at a very early date from Asia Minor.

While the genus *Vitis* is usually accepted to-day in its widest sense as adopted by Bentham and Hooker, in most gardens and nurseries it is still the practice to separate the *Vitis* proper from the *Ampelopsis*.

THE TRUE VINES.

V. Coignetiae, a Japanese species, is the most beautiful of all the true Vines in its autumn colouring. It has large leaves up to 10ins. or 1ft. long and 5ins. to 10ins. wide. The growths are very vigorous, trailing over tall trees and, gorgeous in autumn owing to the scarlet and crimson colouring of the foliage at that season. This is not an easy Vine to propagate except by seeds. Unfortunately, plants from seed vary greatly in the amount of autumn colouring they take on. Layering is a slow method for a plant that is in such demand.

The plant which is frequently grown as *V. Thunbergii* is one of the best forms of *V. Coignetiae*.

The true *V. Thunbergii* of Siebold is a much less vigorous climber, easily distinguished by its deeply lobed and much smaller leaves, which vary from 3ins. to 5ins. long and wide. It colours a golden scarlet and is quite one of the best Vines of moderate growth.

Several forms of the Common Grape Vine, *V. vinifera*, have very attractive foliage. Variety *purpurea*, the Purple-leaved Vine, has bronzy purple leaves in summer, changing to a rich claret red in autumn. It is a very valuable and reliable climber to plant for colour in the garden. Variety *apiifolia* (syn. *laciniosa*) has been given the popular name of the Parsley-leaved Vine in reference to the prettily cut foliage; var. *sylvestris*

TYPICAL LEAVES OF VITIS COIGNETIÆ AND V. THUNBERGII (TRUE).

is similar in leaf to the Common Grape Vine. It takes on in autumn brilliant tints of golden orange, scarlet and crimson.

V. amurensis, the Amurland Grape, is a vigorous growing Vine in the way of *V. Coignetiae* and, like that species, it colours well. *V. armata* and var. *Veitchii* are luxuriant-growing climbers introduced by Mr. Wilson from China. *V. pulchra* (syn. *flexuosa major*) has in summer deep green leaves which change before falling to orange and crimson.

V. megalophylla is a vigorous Chinese Vine with very large bipinnate leaves 2ft. to 3ft. wide and long. In its luxuriant growth and ample leafage it is one of the most striking of all hardy Vines. *V. heterophylla* has a very variable leaf, being in some forms deeply lobed, but the foliage varies greatly even on the same plant. The most attractive form is that known as *humulifolia*, which in warm sunny positions, especially against a wall, produces quantities of turquoise blue fruits. The var. *elegans* (variegata of some gardens) does well against a low wall, the variegated pink and white leaves being very pretty. *V. aconitifolia* is a Chinese species with attractive deeply cut leaflets borne on long slender stems. *V. flexuosa* has rather small foliage and is a native of China, Japan and Korea. The variety *Wilsoni* is more ornamental, with deep green leaves which are purple beneath when young.

THE AMPELOPSIS SECTION.

There are two distinct types among the forms of the Virginian Creeper, which is one of our most popular climbers. The true *V. quinquefolia* is a self-clinging plant, having discs at the ends of the branched tendrils. In nursery catalogues the names *V. Engelmannii* and *V. muralis* are sometimes given to this plant. The climbing plant so much cultivated in town and suburban gardens, and which changes to gorgeous scarlet and crimson in autumn, is *V. vitacea*. This must be supported at first until the rapid growth of the trailing shoots permits of the tendrils seeking and finding supports to which it can cling. There is not a great deal to choose between the two as regards autumn colouring, the one without discs which trails over arbours, verandas and outhouses hanging down to form thick screens or curtains of growth is, however, perhaps a little the brighter. The important point is to obtain the true *V. quinquefolia* if a self-supporting

climber for walls is required. The form with hairy shoots and leaves (var. *hirsuta*) is self-supporting, while the large-leaved variety major and the deeply toothed variety *laciniata* (syn. *incisa*) belong to *V. vitacea*.

V. inconstans, the beautiful self-clinging climber so very largely grown as *Ampelopsis Veitchii*, needs no recommendation. Very easy to grow, it rapidly climbs to the tops of tall buildings, giving a wealth of foliage in summer, which changes before it falls in autumn to varying shades of gorgeous orange-scarlet and crimson. The variety *Lowii* is a smaller-leaved elegant climber with deeply lobed foliage. A form having rich wine purple leaves has been given the varietal name of *purpurea*.

V. Henryana, at least at Kew, is on the borderline of hardiness, but thrives and grows very freely on a north-west wall. It is a native of China, and is named in compliment to Mr. Augustine Henry, who discovered the plant in 1885; but it was not introduced until 1900, by Mr. Wilson. It belongs to the *quinquefolia* section, and attaches itself to a wall by means of the disc-like appendages to the tendrils. The markings of the leaves, deep velvety green with silvery, pink and red midrib and veins, give to this Vine a very attractive appearance. The foliage changes to claret red before the leaves fall. Another allied species with purplish stems and foliage is *V. Thompsonii*. As a pillar Vine this species is very ornamental.

If asked to give a selection of the best ten ornamental Vines my choice would be *V. Coignetiae*, *V. vinifera purpurea*, *V. humulifolia*, *V. megalophylla*, *V. vinifera apiifolia*, *V. quinquefolia*, *V. inconstans*, *V. Henryana*, *V. aconitifolia* and *V. pulchra*. A. K.

SOME PLANTS OF A WEST COUNTRY GARDEN

DURING the cold and dreary days of rain that accompanied the equinox, and survived it, there were few such cheerful things in the rock garden as the *Satureias*. If nothing loves the sun better than these little southerners certainly nothing maintains so dauntless a spirit as they do under the most distressing conditions. In the greyest weather their fragrant foliage, always so green and glossy and fresh, and their spikes of white or pale lilac flowers, suggest their sunny Mediterranean homes, and all they ask is a poor, stony soil in which their near relations, the *Thymes*, delight. These little bushlings are the more welcome at this season since most of the lesser labiates pass with the summer, always excepting our old friend, *Calamintha alpina*, which still has velvet lips of violet to offer to any wandering bee which happens to be abroad at so late an hour.

In giving credit where it is due to such children of the sun as have proved their capacity for enduring the sort of welcome that our autumn this year has thus far accorded them, mention must be made of *Hunnemannia fumariifolia*. This bears a cousinly resemblance to *Eschscholtzia californica*, and is a Mexican species of remarkable beauty. Though a perennial, it is too tender to stand our winters, save, perhaps, in the most favoured localities. But it may be easily grown as an annual and, as such, it fully merits a wider appreciation than it now enjoys. It is an erect-growing plant of about 2ft. in height with finely cut foliage like that of the Common *Eschscholtzia*, but bluer and of more substance. The large bowl-shaped flowers are of a full golden yellow with a rich orange centre, and the most remarkable point about them, after their undoubted loveliness, is the long time they last and the brave way in which they will remain fully open even in wet and cloudy weather.

Speaking of annuals reminds me that it does not do always to despise these plants of a class that suggests a phase of gardening which some of us may have "gone beyond." I am inspired at the moment to these heights of magnanimity by certain very happy clumps of the Common or suburban *Lobelia* which have cropped up in all manner of unexpected places. That these strays are self-sown I have already implied. This may of course be their extenuation and the *raison d'être* of my own benevolence towards them. But no matter how much one may abhor the formal edging or the dotted carpet when made of this popular bedder in the wrong place, that is no reason why one should not extend hospitality to the single plant in the right one. However, *Lobelia erinus* here turns up like a bright-eyed stowaway every year, and in sun or shade, good weather or ill, will accompany the season to the end with its deep speedwell blue.

Having made of August a well deserved holiday month, *Papaver atlanticum*, usually the first of its race to flower with us, throws up a fresh crop of its grass green, hairy leaves in September, these being followed by 2ft. flowering stems of stately bearing. These latter are frequently furnished with a few leaflets near the base, where also they may branch into twin stems which bear at their tips the nodding single blooms whose glowing orange terra-cotta is one of those shades of colour which harmonises with most satisfying effect in the autumn garden. Though it is said to seed too freely in some gardens, *P. atlanticum* is a perennial which we have never found aggressive in that respect. It keeps us supplied with a reasonable quantity of seedlings which have a happy way of appearing in convenient places, often beneath the shade of trees.

Also in an "autumn brown art shade," very much in keeping with the season, is that quaint

iridaceous plant *Cypella Herbertii*, but its curious tawny gold is scarcely so refulgent as that of the Poppy. Though one of those South Americans of the *Tigridia* class which usually do quite well for a season and then depart, *C. Herbertii* has proved quite permanent here. It has got its bulbs hidden away among the roots of an old *Fuchsia* and every season sends up through the lower branches of the latter its thin, wiry stems and sparse, grassy leaves. These stems terminate in the strangely fashioned, three-parted flowers during the later summer and a succession of these is maintained often until October.

Antholyza paniculata, another *Irid*, closely allied to *Montbretia*, must also be numbered among these late flowers which give back the fires of autumn in glowing hues, and its crimson-scarlet flower sprays are extremely effective in woodland. Still fiercer in tone, rivalling even the *Kniphofias*, is *A. crocosmaeoides*, which unfurls its scrolls of intense orange-scarlet at the same time. Both of these are noble, broad-leaved plants of 2ft. or more in height, and their semi-rhizomatous bulbs, if one may so describe them, are as hard to kill in our light soil as the most stubborn *Montbretia* corm.

Like the above, *Schizostylis coccinea* is a South African, yet it is absolutely hardy here. As a matter of fact, it has proved too robust for association with plants of more gentle birth. So to the woodland it went some years ago, where, in an open spot, it grows among grass and other herbage, thriving with seemly vigour and not demanding that all too frequent attention with the pitchfork that it is wont to do in places where life is too easy.

Though herbaceous plants of the usual border description are not a prominent feature with us, one reason being that there are hardly any borders, there is one which we should not like to be without at this season, and that is *Aconitum Fischeri*. The very large blossoms in a bright violet blue—almost a pure blue in subdued light, of this Monkshood, together with the broad and ample foliage, create a most imposing effect. The stems, moreover, which rise to 3ft. or 4ft., are rigid enough to stand without staking or tying, and it is by no means an uncommon occurrence to have *A. Fischeri* in flower throughout the whole of the autumn. This is, I think, a finer plant than *A. Wilsoni* and it is of the easiest culture.

For a good many years that dainty little Rock Rose, *Helianthemum lunulatum*, has given us an autumn crop of blossom that is by no means inferior to its earlier efforts. This does not appear to be a common species, but it is one of the most delightful of its cheerful race, making a semi-prostrate bushling about 9ins. in height and twice as much in width, close-set with small, oval pointed leaves all shimmering with silver. The bright yellow flowers which appear all over this pretty foliage are about $\frac{1}{2}$ in. across and each petal bears at its base a tiny crescent of orange by which the true plant can be distinguished.

In a cool corner of the woodland the shining, bay green foliage of *Gaultheria procumbens* has been bright for some weeks with the pearly white flowers of this American Wintergreen of which the red fruits, will remain as far through

the winter as birds and mice will allow. More uncommon is *G. nummularioides*, whose long, slender, creeping stems, thickly coated with rusty hairs, bear a double row of round, dark green leaves which grow smaller towards the tips, somewhat after the fashion of those of *Lysimachia Nummularia*. Though it grows vigorously, making large mats, and blooms with commendable regularity every September, this *Gaultheria* has not yet ripened any fruit with us. *G. trichophylla*, like the last mentioned, is a Himalayan, but it appears to be absolutely hardy, and its glossy green, healthy foliage and lowly, creeping habit make it a first-rate little woodlander for associating as a carpeting with other ericaceous plants. *G. trichophylla*, moreover, bears fruits of most remarkable dimensions for so small a plant, and of a clear, porcelain blue.

Then there is the very uncommon *G. pyrolaefolia*. This is only a recent addition to our garden, but having once seen it (among Mr. E. C. Buxton's treasures) it had to be acquired forthwith, for it possesses not only a full share of that peculiar fascination which the genus has for some of us, but the charm that belongs to distinction and rarity.

NORTH WALES.

SIEBOLD'S PRIMULA

THE plant usually grown in gardens as *P. cortusoides* is almost always *P. Sieboldii*, a handsome but not over-hardy Japanese species, of which there are quite a number of excellent forms in

THE CHEERFUL SPRING-FLOWERING PRIMULA SIEBOLDII.

commerce, with flowers varying in colour from pure white to deep purplish rose; some of the sorts, and those not the least handsome, have fringed petals. It is rhizomatous, and these rootstocks are very easily damaged by frost, especially in wet soils. For colonising in fairly open woodland, however, or for a sheltered corner in the rock garden this spring-flowering species is first-rate.

SOME SUITABLE PLANTS FOR OLD WALLS

I DO not intend in these brief notes to deal with dry wall gardening as it is generally understood by the lover of this form of growing plants. I refer chiefly to the utilisation of the top of any wall suitable for the purpose and in suitable surroundings. I well remember plants being established on a wall thirty years ago. When on a visit to this garden recently I saw many of the original plants, many several feet high, others compact tufts either embracing the top or depending gracefully from both edges and clothing several feet of the wall on either side. Little colonies of *Sedums* and *Saxifrages* were most attractive, and one felt one could linger by this wall and enjoy its beauties for a long time. Walls so treated should harmonise with their immediate surroundings.

If the wall to be dealt with is built of bricks with a coping of bricks on edge, there will be no necessity for dislodging any of the bricks. Bricks on edge should be placed lengthwise to form a narrow space in the centre to contain some soil and the roots of the plants. At intervals of 27ins. cross bricks should be built in to bind together the two courses placed on edge. This applies to a 9in. wall, a 14in. one may have containing bricks placed flat, and old stone walls should be treated similarly, only in this case more informality of arrangement can be secured. Any interesting plants now growing on the wall should be retained if they are conveniently placed.

Now we must consider the question of planting and the soil to be used. Old mortar rubble will be needed, and should be procured even at some trouble. One peck of lime rubble to 4 pecks of soil will answer the purpose. It is a mistake to use ordinary garden soil; really good fibrous turf is the best because it is not so readily scratched away by birds and the roots of the plants are left undisturbed. Immediately on the roots, or the soil covering the roots, of each plant place a small stone or fragment of brick. In the hollow places of the wall where it is intended to establish any plants to furnish the sides, a small plug of clay will help to make the tiny plants secure; this dab of clay is in addition to the soil pressed in.

The early part of spring is the best time to establish wall plants, but the wall must be prepared for them some time beforehand. The following are suitable kinds for the beginner to select from, but expert wall gardeners will with great success furnish a wall with many others. Small specimens are more likely to succeed than large ones. Newly rooted cuttings will with great care do well, but they require extra attention. Seedling and other *Pinks* are charming, and other suitable kinds

include *Nepeta Mussini*, *Sedums*, *Sempervivums*, *Encrusted Saxifrages*, *Helianthemums* (Sun Roses), *Erinus alpinus*, some of the subulata section of *Phloxes* (flowering early in the year), *Alyssum saxatile*, dwarf *Campanulas*, *Aubrietias*, double and single flowered *Arabis*, *Iberis* (*Perennial Candytuft*), *Alpine Wallflowers* and *Arenaria balearica*. Small-flowered *Fuchsias* do well and also *F. Riccartoni* in the case of strong walls.

There are many really old, partly broken down walls in different parts of the country belonging to ruined buildings and in quite romantic settings, covered mainly with lichen and mosses. Such

old structures would look charming were they clothed with Foxgloves, dark red and yellow Wallflowers, Honesty and clumps of *Cerastium tomentosum*.
GEORGE GARNER.

GARDEN DESIGN.—I

NOWHERE is greater interest taken in the development and beautification of country estates than in this country. The Englishman is essentially a lover of his home, and his traditional good taste is the result of centuries of culture. This has enabled him, generally speaking, to retain what is good and to develop in the most careful way his ancestral demesne. Equally is this the case in the making and development of more recent acquisitions. These are generally of smaller extent than formerly, but evidence a beauty of design and care in their making that were sometimes lacking in the work of earlier days.

Proper proportion and relationship of the several parts are the secret of success both in estate planning and in the designing of gardens. The extent and treatment of the grounds must be in harmony with, and form a satisfying setting to, the residence, and from the entrance gates to the extreme limits a sense of harmony and fitness should everywhere be felt.

Tastes vary greatly, and what is the recreation of one man may be the height of boredom to another. Almost everybody, however, loves a garden, and it is, or should be, the ambition of

everyone to make his surroundings suitable and as beautiful as they can be made. Local conditions will very largely govern the design of the grounds; for example, a hillside garden would probably be treated as a succession of terraced gardens, and very beautiful results may be obtained by doing this. Surroundings should be carefully studied; the principal windows of the house should command and frame the most pleasing views both of the grounds and of distant scenery.

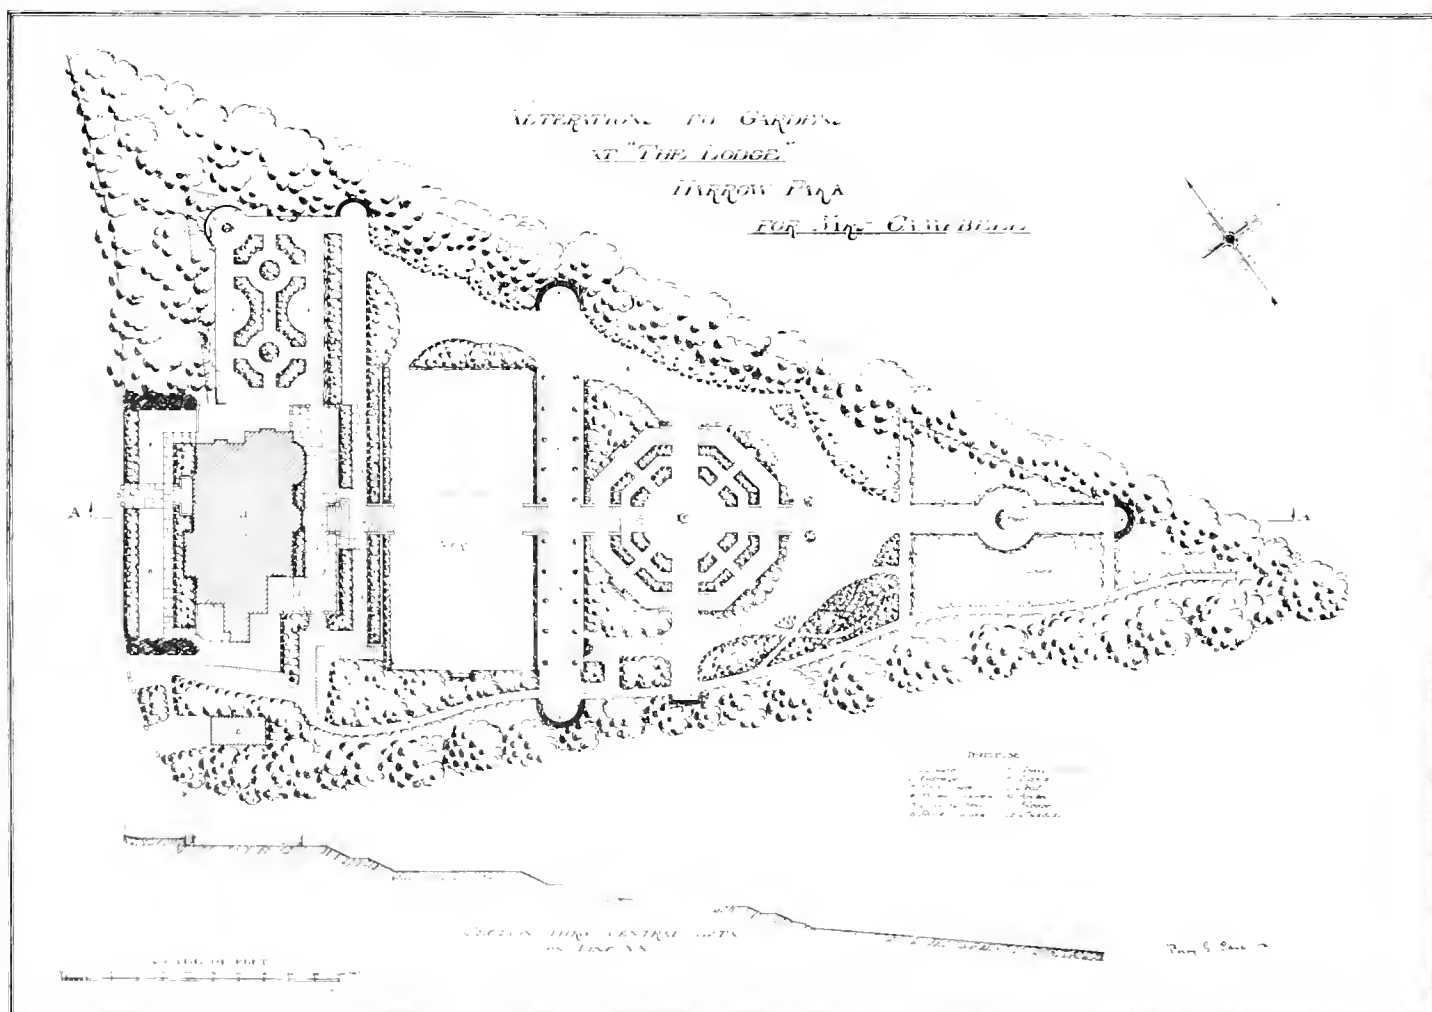

Even if some parts of the country are not notably beautiful, the rich verdure of lawns and trees makes the English countryside generally pleasing, but where this is not so and where, it may be, smoky chimneys of manufacturing towns have to be screened from sight, unsightly surroundings should be blotted out, and interest be created within the limits of the grounds.

Modern gardens generally shew great care in their arrangement and are more beautiful than was formerly the case, excepting of course those older ones of outstanding interest and charm. A finer and more critical taste and appreciation govern their design; there is a greater contrast between their separate parts, and a more carefully planned harmony of colour and elaboration of detail.

Some kind of terrace (or terraces) is generally an essential connecting link between the residence and the grounds, and seldom, if ever, is a pleasing impression created by stepping directly from the house into informal gardens. This being so, a properly planned terrace (or terraces) will usually relate the house to the grounds in the best possible way.

Some definite conception or idea of what is to be done should always govern the planning. The treatment of any site offers a very wide range of choice. The architectural character of house will be the *motif* or keynote governing the treatment of the gardens. The fitting setting for the mansion will be the ordered stateliness of its park-enclosed grounds, while smaller places will have their equally beautiful, even though less elaborate gardens. The tendency, in these days of high taxation and expenses, is to have smaller, but well appointed houses in beautiful, if less extensive grounds than was formerly the case. There is much to be said in favour of these compact estates; they are often owned by men who are away for a considerable part of their time and, if properly run, their management is a source of pleasure and relaxation instead of, as might easily be the case with larger places, becoming actually a tax upon the energy and leisure of their owners. Country life is to most people a healthy life, full of interest, and the making or improvement of an estate, even if it is to be a small one, is a source of lasting pleasure.

Consequent upon the reduction in cost, the building of new houses is again commencing,

SHews FORMAL AND INFORMAL PLANTING IN A SMALL GARDEN.

and an impetus is given to the adaptation and modernisation of older places. Most of our old farmhouses and other buildings may be thus treated. There is something very attractive about many of these old farms surrounded with their farm buildings. They are full of local colour and, where a small estate only is required, they may be made to possess a charm and picturesque-ness entirely their own.

Careful attention should be given to the choice of the site for a new residence. The principal rooms should command the most pleasant views and should have a southern or western aspect. Shelter should be provided by planting belts of conifers or of conifers and deciduous trees to shut off the north and east winds, and at the same time to give that air of comfort and seclusion that is lacking in the case of houses without trees. Trees should not be near enough to darken the windows, to make the house damp, or to interfere with foundations.

Perhaps the best, even of smaller as well as of larger grounds to-day, consist of an arrangement of formal gardens in an informal setting, this informal setting being in what is known sometimes as the "landscape" style. The word landscape, as applied to garden planning to describe the opposite of formal design, is a curiously misleading one, and is really more applicable to the grouping of forest trees in parks than to other forms of garden design.

To return to the terrace and formal gardens, like every part of the grounds, and to an even greater extent, these will be governed by the architectural character of the residence. Often one may plan a paved garden as a part of or near to the principal terrace, and here should be masses of the choicest plants and richest colours. One should be careful when making or planning different gardens to arrange the plants in their proper places, for although a number of plants may be equally at home in gardens that are quite different in character, yet the different gardens should have each their own particular character to a very marked degree. The rose garden will, excluding carpeting plants of course, be for Roses alone and, except for Rose species and Rambler Roses, these beautiful plants will not be grown in other parts of the grounds. Herbaceous borders will be the home for the numbers of beautiful hardy plants that are procurable nowadays. It should be remembered that plants vary very much in character, and that there is as much difference in their texture as between rich silks and velvets and the thinnest of cotton, and that it does not do to mix these different qualities too freely. There are parts of the grounds, such as on the terraces and in paved gardens, where, although the planting may be chiefly of perennial plants, yet in its effect it is far richer than the ordinary herbaceous border.

Suitable vistas should be planned for the longest distances through the principal parts of the grounds, and even though it is possible for the eye to travel for considerable distances along their lengths, the different gardens as one enters them must always surprise by change and contrast of beauty, so that one goes from formal to informal and wild gardens, if the grounds are sufficiently extensive, always feeling harmony of proportion and that every part is happily related to its surroundings.

The design given illustrates the planning of a comparatively small garden. In its contrast of formal and informal design and in the varying character of its separate gardens it shews also the results that may be obtained from a terraced treatment of ground that is naturally sloping.

PERCY S. CANE.

(To be continued.)

CORRESPONDENCE

JAPANESE CHERRIES.

THE statement made in THE GARDEN for September 20 that "it is now easier to obtain the Oriental Cherries on suitable stocks than was the case until recently" is of great interest to me. For a number of years I have been striving to get

here in my collection.—COLLINGWOOD INGRAM, Benenden.

GENTIANA FARRERI & G. SINO-ORNATA.

IN reply to "H. M. N. R.'s," Yorks, enquiry as to how I produce ripened seed of *Gentiana Farreri*, I may say my plants start flowering in the

GENTIANA SINO-ORNATA AT GLENDFVON, PERTHSHIRE.

Japanese Cherries worked on the stock recommended by Wilson, i.e., *P. serrulata* var. *sachalinensis*, but up to the present I have been wholly unsuccessful. Any information that would enable me to do so would, therefore, be very acceptable. As the above-mentioned North Japanese form is a vigorous and hardy parent of some of the finest double varieties, for these near relatives it is no doubt an ideal stock, but I think it still remains to be proved that it is equally suitable for the *P. Lannesiana* varieties. The plants I have imported from Japan appear to have been worked on two different stocks—some on an apparently small form of *P. serrulata spontanea* (which seem to have a decidedly dwarfing influence) and some on a form of *P. Lannesiana* (probably the undesirable *Mazakura*—cf. Wilson's "Cherries of Japan," page 52). Personally, for this country, I prefer *P. Avium* to either of these for the cultivated varieties of *P. P. serrulata* and *Lannesiana*. I choose this stock for the same reason that I choose Plums for my fruiting Peaches—it is more "at home" in my somewhat chilly soil. As the Japanese Cherries vary considerably in vigour, to avoid the possibility of unsightly swelling or restriction at the point of union it is best to work them low down on the stock; moreover, they usually do better when so worked. With regard to the so-called Rosebud Cherries, I have in cultivation a distinct variety which you omit from your list. This charming and very floriferous little Cherry is called *Usubenibigan* by the Japanese, and has been given the varietal name of *alborubescens* by Miyoshi. Curiously enough, it is not mentioned in Wilson's brochure. I would like to take this opportunity of pointing out that *Ichio* is a Japanese synonym for *Hisakura*, and not a separate form as is suggested by your article. Furthermore, according to Wilson, *Sirotae*, and not *Seuriko*, is the native name for the Mount Fuji Cherry. *Seuriko* is an exceedingly handsome single variety with large bluish pink blossoms, specimens of which are now growing

middle of August—the photograph you published (page 493) was taken on September 2—and are still opening their flowers. *Gentiana Farreri* has a great attraction for the bees, which appear to fertilise the flowers very freely, and I have secured a good quantity of seed this season. The late Reginald Farrer in his book "On the Eaves of the World" says: "A distinct line is followed in the seed of the *Gentians* of Tibet: when the blossom goes over, the style protrudes further and further out of the mouth till about twice the length of the carpel, and while the collector is vainly hunting for the seed at the base of this, where the ovary should surely be, and grows weary with disappointment at never finding any, lo! suddenly a little oval knob at the very tip of the style gapes open with two lips and there is the seed after all, and if you are not wary it is out and away while you watch." The seed of *Gentiana Farreri* ripens very quickly, within about ten days after the flowers fade, and during wet weather the seed is very liable to decay. I find it best to look over the plants twice a week, open the faded blooms, and if the seed-pod is about ripe, pick it off and dry in the sun. In a few days the tip of the seed-pod splits open and the seed falls out. The soil in my garden is of a peaty nature, we are about 700ft. above sea level, and being at the foot of the Ochil Hills we get a good deal of moisture during summer, which I think is the reason my plants grow and bloom so freely and set seed. I enclose a photograph of *Gentiana sino-ornata* growing in my garden. This photograph was taken four weeks later than that of *G. Farreri*. *G. sino-ornata* increases very quickly with me, and I find the best way to propagate it is by division in the spring. Being so late in flowering it sets very little seed.—A. H.

I WAS very much interested in "A. H.'s" paragraph regarding *Gentiana Farreri* which appeared in THE GARDEN of September 22, and perhaps all the more so as I had quite recently

had a small lot of the Gentians at Glendevon. What was most as being unusual was the statement that this lovely Gentian ripened its seeds at Glendevon every year, and when sown in 1911, produced flowering plants in the autumn of the year following. Hitherto we have looked on Gentian seeds as being exceedingly slow in germinating, taking about a year to baird, consequently "A. H.'s" experience quite upsets all our ideas in this connexion. Being a late-flowering plant, it would be interesting to know how your correspondent manages to obtain ripe seeds. Do they carry the seed-pods through the winter and ripen the seeds in spring and, if so, do they require protection from the frosts and storms of winter? I think it would be exceedingly interesting, as well as instructive, if "A. H." would, in the pages of THE GARDEN, give a *résumé* of his method of culture from seed sowing to seed saving of this charming plant. I feel sure, considering the success he has attained in the culture of this Queen of Gentians, that a few notes regarding his treatment would be appreciated by all lovers of alpine flowers.—ALBYN.

[Our correspondent's point about the ripening of the seeds is covered in the previous letter.—ED.]

A GLADIOLUS SOCIETY?

I WAS pleased to see in your issue of the 6th inst. Mr. Payne's note *re* the formation of a Gladiolus Society. There is abundant evidence that the Gladiolus cannot much longer run its course of ascending popularity without the organised help of such a body, because, as Mr. Payne points out, the need is already urgent for some controlling power, not only to classify and register new varieties, but to put a staying hand on the impetuous rush of mediocre or even worthless flowers on the market. Some folks seem to think that any Gladiolus with the blue blood of the *Primulinus* type running in its veins is worthy of a place among the elect. Both this season and last I have seen dozens of *Primulinus* seedlings bearing flamboyant and high-flown names that should never have been looked at the second time in the seedling bed. That sort of thing is sure to injure the justly increasing popularity of the Gladiolus, and I can think of no other means of encouraging the production of really good varieties, and its *concomitant contra*, than through the operations of a society having the care of this beautiful flower in charge. Yet we cannot forget the inglorious demise of the English Gladiolus Society during the sad years of war not so very far behind us, and it would perhaps be wisest first of all, before making agitation towards a definite scheme, to invite the opinion of as many of your readers as possible, so that some estimate could be made of the strength lying behind the desire to rejuvenate the old society. Built on a solid foundation, I feel sure a great deal of good and useful work would be accomplished by its activities, but we must not risk another debacle.—J. L. GIBSON.

At Holland Park on Tuesday, October 2, when I was looking at Mr. Chapman's exhibit of Tomatoes, three gentlemen behind me were having an argument as to the name of a Gladiolus. The first stated, "That is not Marshal Foch!" but the other two were equally certain that it was. Shortly afterwards I looked at the flower and it was named "Kunder's Marshall Foch," a large open flower of a pink colour with a darker blotch. This flower was on Messrs. Lowe and Gibson's stand. A little further along I came across another Gladiolus on Messrs. Artindale's stand named "Marshal Foch," but this was a lavender pink. Continuing along I came to Messrs. Kelway's stand, and I cast my eye along to see if there was

a Marshal Foch present, but did not detect one. However, on picking up a list, I found yet another. "Kelway's Marshal Foch—very deep scarlet self." Would a Gladiolus Society prevent such a duplication of names?—PERPLEXED.

WHAT LILIUM REGALE CAN DO.

WHEN Mr. E. H. Wilson introduced this glorious Lily from Western China it was a moot point as to how hardy and how floriferous it would be in our rather trying climate. Shown first, I think, in 1912, it was seeded, and in 1916 at the Holland House Show the progeny of 1912 plants were exhibited with one or two flowers on a stem. A year or two ago the bulb sellers' catalogue modestly put the number of flowers from two to five, but five flowers on the stem has been for some years quite an ordinary occurrence. Last year one of my seedlings, from one of the plants which was at Holland House, had eight flowers and ripened seven capsules, which stem is now in the Manchester Museum. This year, the same seedling, or another one, produced two stems from one bulb which had respectively fifteen and twelve buds, but which I disbudded to nine flowers each. The accompanying illustration shews this plant in full bloom. The flowers do not look quite so well as they should do, as all the blooms have been de-anthered for cross-fertilisation. This Lily so splendidly and readily produces seed that it is a very good subject for experiments in that direction.—J. H. WATSON.

THE FIFTY BEST ALPINES.

AS a keen lover of alpines I submit for the favour of your criticism a list of fifty best alpines. Most of them I have successfully flowered, though one or two are not perhaps correctly described as alpines. Opinions of other readers would be of great assistance. The list is as follows: *Androsace sarmentosa* Chumbyi, *Aquilegia alpina*, *Arenaria balearica*, *A. montana*, *Asperula suberosa*, *Azalea procumbens*, *Campanula Allionii*, *C. carpatia alba*, *C. cenisia*, *Cyananthus lobatus*, *Cypripedium Calceolus*, *Cytisus kewensis*, *Daphne Blagayana*, *D. rupestris*, *Dianthus alpinus*, *D. neglectus*, *Douglasia levigata*, *Dryas octopetala*, *Genista Ardoinii*, *Gentiana Farreri*, *G. sinornata*, *G. verna*, *Geranum argenteum*, *Geum Borisii*, *Gypsophila cerastioides*, *Linum salsoloides nanum*, *Lithospermum prostratum*, *Lysimachia Henryi*, *Omphalodes Lucilie*, *Ononis cenisia*, *Oxalis enneaphylla*, *Papaver alpinum*, *Pentstemon Davidsoni*, *Petrocallis pyrenaica*, *Phlox subulata Vivid*, *Potentilla nitida*, *P. fruticosa Farreri*, *Primula nivalis*, *P. rosea*, *P. Winteri*, *Ranunculus Nathaliae*, *Ranunculus glacialis*, *Saxifraga Aizoon Rex*, *S. Bursleriana Gloria*, *S. Faldonside*, *S. longifolia*, *Shortia galacifolia*, *Silene acaulis*,

Soldanella Ganderi and *Viola Bertoloni*.—PURLEY.
[The topic is an interesting one. Perhaps readers will give their selections.—ED.]

RHODODENDRONS AND STABLE MANURE.

IT seems to me a kind of unwritten law, but one however, which is most rigidly adhered to, that Rhododendrons are shrubs which do not require any manure, do not like it and, in truth, are better without it. Certain it is they do not get it in one case out of a hundred. The second thoroughly ingrained idea is that they will not grow in anything but peat. From this latter statement, however, there are a few dissentients; some realise that loam or loam and leaf-mould will do almost equally as well. Now, when I recommend an application of strong doses of stable manure, I

TWO FINE SPIKES OF LILIUM REGALE ON ONE BULB.

well know I am stirring up a veritable nest of hornets around my head, and one worthy baronet at least will, doubtless, be on the wing, pursuing me like an angry bee ever ready with its sting. Fortunately, I have the ammonia, the counter-irritant, at hand, as I speak from personal experience on the manure question. No doubt, leaf-mould, peat, decaying branches and top-dressings of cut grass are all helpful in their way, but recommend me to a good barrowful of stable dung if one wants healthy, flowering plants. In the case of old shrubs, it is better applied about 18 ins. or 2 ft. from the stem, as it is there the young roots will be found ready for food. My little experience is gained from among the Himalayan section of "Rhodos," but as, comparatively speaking, they are grown only by a few, I will take for example that favourite hybrid Pink

Pearl. Personally, I think this is very much over-rated, being a bad pink at the best. One of the most convenient spots to study the little tragedy is the villa garden, where, some fine spring morning, the shrub will make its appearance in the centre of the front plot, with very possibly five plump buds on it. In due time there are five large trusses of bloom, one of which perhaps is given to "a dear friend" and the remaining four, seed-pods and all, left, which certainly tends to accelerate the fate of the plant. Next year the plant is rather bilious-looking, with, possibly, one rather sickly bloom, and the owner begins to think it is not "hardy." In the third year there are no flowers and the shrub has a very jaundiced look indeed, so that the owner is now quite convinced that it is not hardy; but he is so charmed with its size, etc., that bang goes another 7s. 6d. on a new plant. The truth is the poor plant has bloomed itself to death and, having no nourishment to speak of, gives up the struggle for existence. If the owner had only given the poor thing a good dash of stable manure, all would have been well, and so it would have been in hundreds of other cases. That Rhododendrons require manure, and plenty of it too, is my experience. When planting I have often given them a liberal sprinkling of half-inch bones, and if transplanted in a few years, the bones will be found hanging to the roots like barnacles. I think, therefore, they like bones, though bones must contain a large percentage of lime. I hear someone say "Disbud the plant freely." Well, possibly, but as the Pink Pearl owner, naturally, wants blooms, he had better keep the buds, put on the manure, and continue to enjoy his plant. I have no experience of a limy soil, but would not be very much surprised if, given plenty of cow manure, they could be induced to thrive in it also. As a test to the foregoing remark I have just come in from planting R. Nobleanum in a heap of old lime rubbish and, of course, with an ample supply of cow manure, and will see what result.

I notice small white specks appear on the upper side of the leaves of "Rhodos" (or at least a number of them) when the plants are robust in health, and these on well manured plants are very prominent. For choice I think the manure is better applied immediately after flowering, as it is then the new wood is made and the unsightliness of the dressing is little noticed. The only fault I find with heavy dressings of manure, however, is that some of the more tender plants are not so well able to stand severe winters as those growing without it, but on the seaboard, where frosts are less prevalent, this is of little moment. One of the Rhododendrons which seem to revel in manure and look like saying "Thank you" is that charming little precocious child of spring, born of such excellent parentage as R. ciliatum and R. dauricum, called *præcox*. How charmingly it is named!—FORMAKIN.

THREE GOOD EARLY MICHAELMAS DAISIES AND A LESSON THEREFROM.

WE popularly call the race Michaelmas Daisies, but this year only a few of my large collection were in bloom on Michaelmas Day. The big show will most likely be in St. Luke's "little summer," and I would not like to say that all will be over at Martinmas-tide. Of those that appeared in their full glory at the conventional day the two that appealed to me most were the old Feltham Blue and the new Pioneer. They are graceful in habit, free blooming, light and airy, and their flowers are not monstrosities! Barnum, how well you gauged human nature in the monstrosities you gathered together for your shows! There is the taint of this old Adam in all of us I fear, and so we bring ourselves to like my third

choice, Lavender, which is very beautiful in colour—being a real pale lavender—but which, alas! is half inclined to be a double and in consequence the outline of what I conceive ought to be a clean cut central mass of yellow is blurred. Lavender has flowers of quite an "out-size" in Michaelmas Daisies (many measuring 2ins. across) and they are freely produced. The variety has been raised by Mr. Ballard of Colwall, Malvern, whose name is in every mouth as one of our great raisers of Michaelmas Daisies. So was Pioneer. This is the purest pink that I have ever come across in this race of plants. I compare it with the pure pink that we find in what I believe to be the typical *Alonsoa Mutisii*. There is not a vestige of blue in it. Pioneer, too, is anything but a monstrosity. Mr. Ballard has told me its parentage, and I only hope he will go on and give us others of this type. Let me assure him there are people, even if they be a small minority, who do appreciate dainty plants and flowers. Feltham Blue is like Pioneer in its general habit and in its type of clean-cut flower. The orange yellow centre surrounded by the rich blue-purple ray florets make a very beautiful combination. Why is this variety being gradually shelved? I answer: "The love of monstrosities and the worship of size."—JOSEPH JACOB.

THE GENTIANELLA.

I AM pleased that my good friend Mr. Ingwersen raises a discussion on this general favourite, which, I hope, will lead a step forward. It is a very difficult problem, to popularise the name of a foreign plant which, although known to all growers of alpenes, is not to the man in the street. Mr. Farrer, as a young man, was opposed to the ideas emanating from Wardour Street, but later he became a renegade from his own convictions and merrily invented English names for plants known only to a small section of enthusiasts. I will only refer to the "Eaves of the World" and the vivid christening of the genus *Meconopsis*, surname and others. If *Papaver* stands for Poppy, *Meconopsis* does not. *Mais, revenons à nos moutons!* I share Mr. Ingwersen's views on the tricky character of *Gentianella*, so frequently blind, and on the seedlings, which very little from the parents. If you must fail with *Gentianella*, you will do so in every possible position and under varied conditions, as I have proved to my discomfort over ten years. When my friend speaks about his experience with plants in Stevenage, may I tell him that these specimens are *true G. excisa*? The very quality of the flowers shews it. And now I will shock your readers and say that the true *Gentianella* cannot rival *G. excisa* and *vulgaris*. Often *Gentianella* shews white spots near the apex and the trumpet is slaty or tinged with unpleasant green. I will not call it a florist's flower, but certainly man has meddled with it. I have not seen Linné's type specimen, and will assume that he described wild material. It would be instructing to hear which variety or species he did handle. The parentage of our *Gentianella* is very likely correctly stated by Mr. Farrer, and I think he deserves admiration for the lucid way in which he sets out clearly the variations of the different types seen with the eye of the field botanist and practical gardener. *Gentiana excisa* Presl. stands as far away from *Gentianella* as *G. angustifolia*. *Gentianella* is a truly stoloniferous plant, *excisa* is not. The crowns are closely adpressed and it does not ramble like *Gentianella*. The flower is undoubtedly superior to that of the latter. *G. excisa* is not as rare as Mr. Farrer would have it. You can see millions of plants on the upper Bavarian plain at an average height of 6000m., are remainder of glacial periods, and growing in black peat overlying scree. And

there one can take note how it hates manure. Certain meadows covered with flowers in 1914 had lost practically all plants by 1920 owing to wet manuring. We like to believe in symbiosis if we cannot manage a plant. Well, not more than a foot from the blind *Gentianella*, *G. excisa*, *angustifolia*, *vulgaris*, *x Dumoulinii*, *verna* and *astiva* flower and thrive in my garden. But *G. dinarica*, also stoloniferous, fails there too.—P. ROSENHEIM, *East Molesey*.

Gardening of the Week

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Rhubarb.—The general shortage of Apples will no doubt induce people to force Rhubarb in greater quantity than is usual, and as this desirable substitute requires gentle forcing to obtain the best results, an early start should be made. When the stems have decayed, a few strong roots may be lifted, left exposed on the ground for a few days, and then transferred to a cool greenhouse or cellar. Undereath the stage of the former will be excellent. A little garden soil should be placed between the roots and then kept moist. A few roots introduced at intervals of a month or so will keep up a steady supply.

Winter Spinach.—The copious rains in September gave this crop a good start, and now it will be necessary to thin the plants before they become overcrowded. To prevent any waste the thinnings should be taken to the kitchen. Keep the bed free from weeds and decaying leaves, and use the hoe at frequent intervals. A dusting of soot will be beneficial, and if slugs are prevalent a sprinkling of lime between the lines will help to keep them in check.

Seakale.—When the foliage has decayed it should be removed and the crowns fully exposed to allow them to become thoroughly ripened. A few weeks hence the roots may be lifted and the best selected for early forcing.

Mushrooms.—The beds should be producing crops of mushrooms, and if a few cultural details are observed they will continue to be productive for some weeks. The average temperature should be about 60°, but if we get a spell of cold weather 10° lower will be better than employing much fire-heat or fermenting material. Syringe the walls occasionally to keep the atmosphere moist, and when the soil becomes dry it should be given a sprinkling of tepid soft water, using a fine-roset water-can. Overwatering should be guarded against, but the other extreme is also detrimental. Continue to collect horse-droppings for new beds, and turn them over occasionally to allow the rank heat to escape.

The Flower Garden.

Montbretias are useful August and September flowering bulbs, and *M. crocosmaeflora* increases rapidly if left alone for a few years. In time, however, they deteriorate unless they are lifted and the best corms replanted. When the foliage has ripened off, such work may be undertaken, planting the bulbs about 3ins. deep. A light, well drained part of the garden suits them admirably.

Antholyza paniculata may also be lifted if needed and replanted. It will succeed either in the herbaceous border or in a bog providing it is not too wet in winter.

Flowering Shrubs.—Some plants will have filled their allotted stations, and to prevent choice examples from being overgrown it may be necessary to transplant them to another part of the garden. Such work may be done directly the soil is moist enough, and no doubt if early planting is practised the shrubs hardly feel any check. Newly planted shrubs should be examined from time to time to ascertain if they are still firm in the soil.

Rambler Roses.—This section is largely employed for pergolas, arches, tree stumps, fences and banks, and little pruning is needed beyond removing all weak and worn-out shoots. During mild weather the plants should be overhauled, new poles put in where needed, and strong twine used for tying the growths to the supports. Additional plants may be secured and planted at this season.

The Hardy Fruit Garden.

Planting.—Fruit trees may be safely planted during the next few months; it, nevertheless,

is advisable to get them in their permanent stations as soon as possible. Planting ought not to be carried out when the soil is very wet, and the holes should be sufficiently large to take the roots when spread out to their fullest extent. Deep planting is not recommended, and the soil should be broken up so that it will run freely between the roots. The ground should be made fairly and gently treading as the operation proceeds, so that each tree is given a label, preferably a metal one with wire attached to fix it to the tree. Standard trees will require staking directly they are planted, but care should be taken to prevent the support from chafing the stem during rough weather. It is advisable to place some material between the tree and stake where the tie is made.

L. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.).

Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Seakale.—The plants are now in the resting stage, and those intended for forcing indoors should be carefully lifted and packed closely together in sand or sandy soil in a convenient place in the open where they can be protected in the event of severe weather occurring. Any things suitable for root cuttings should be detached and stored as indicated above. To save subsequent trouble, however, these things before being put away should have the thick or upper end cut level across while the lower end should be cut with a slant, thus guiding the operator when planting. A certain portion of the crop may be forced in position out of doors to succeed that forced indoors, and, if judiciously treated, plants forced thus will remain in good condition for several years.

Globe Artichokes.—As these plants are not absolutely hardy, some leaves or other litter should be placed loosely round the neck of each as a protection against severe frost. If any flower stems still remain on the plants, they should now be cut over.

Horse Radish.—It is a wise precaution to lift a certain number of thongs and store them in sand or sandy soil either outdoors or indoors, where they will be conveniently accessible when wanted during severe weather.

Laying Box Edging.—Where box edgings require relaying, the work may be undertaken now with less chance of any failures than when done in spring; moreover, there is generally more time to spare for the work now than in spring. To relay box properly is a somewhat tedious operation, but as it has only to be done at fairly long intervals, it is worth doing thoroughly.

The Hardy Fruit Garden.

Gooseberries.—The work of pruning should be carried through as soon as possible. The old-fashioned system of spurring is now almost entirely abandoned, and the following system is found to produce superior crops, and where it is adopted less damage is likely to be done to the buds by ton-tits. In the case of young partially developed bushes, first cut away any weak or badly placed shoots and, if overcrowded, thin out some of the normal shoots, then cut away a few inches of the miniature wood at the points of the leading shoots which are to form the framework of the bush. In pruning fully developed bushes, first cut away any dead, unhealthy or badly placed shoots; then cut away a proportion of the older leading shoots and encourage young, vigorous ones to replace them. Cut away the miniature points of the young shoots produced during the past season. The two chief points to be aimed at are the maintaining of young, healthy wood and the admission of ample air and light into the bush.

Morello Cherries.—The pruning and training of Morello Cherries should be attended to without delay. So long as the framework of the tree is healthy it should not be interfered with, but as the fruit is borne on the previous year's wood, a supply of young wood should be maintained. Cut away the shoots which have borne fruit during the past season, retaining sufficient young wood to form next season's crop. Nail the young shoots into position, using medicated shreds, and if any of the branches are held too tightly, cut away the shred or tie and replace it by a new one, allowing the branch room to develop.

Planting.—If it is intended to plant any trees or bushes, they should be ordered and preparations made for planting them when received. Autumn planting is preferable to spring planting, as the plants get a good hold of the soil before winter

sets in and are therefore less likely to suffer from the drying-up effect of spring winds. Wherever planting is to be done, the ground should be trenched. Rank manure may be placed at the very bottom, as it will help to aerate the soil, but such should not be allowed to come in contact with the roots. For stone fruits, especially, some old lime mortar has a highly beneficial effect.

The Flower Garden.

Chrysanthemums.—The flowering period being now over, a certain number of plants of each variety should be cut over, lifted, boxed up and placed in a cold frame to furnish cuttings in the spring. When finished give them a good watering with a rose can, and when the water has drained away, dust some soot in among the plants as a preventive against attacks by slugs. Admit air freely except in severe weather.

CHARLES COMFORT

(Formerly Head-Gardener to Mr. Haig, Broomfield, Davidson's Mans, Midlothian).

GREENHOUSE AND CONSERVATORY.

Dicentra spectabilis. This beautiful hardy herbaceous plant is very charming for conservatory decoration. Strong plants should now be placed in 7 in. or 8 in. pots and stood outdoors or in cold frames until such time as they are required for forcing. As they do not stand hard forcing, they should be brought on slowly in a temperature of about 50° maintaining a moist atmosphere. When growing strongly they require ample supplies of water at the root. To keep them strong and sturdy they should be given plenty of standing room and kept well up to the roof glass. By

Begonia Gloire de Lorraine. It may be propagated by means of cuttings during the spring, but many cultivators find this difficult. This is generally due to keeping the cuttings too close and moist. Old plants frequently flower and produce seeds. When they can be obtained, seeds afford an easy and ready means of increase.

Celsia cretica is very useful for the embellishment of the conservatory. Its seed is sown at this time the subsequent plants will flower next summer. Its successful cultivation presents no difficulty, as it grows quite well in ordinary potting compost and only requires the shelter of a cold frame. The plants should be grown on into 6 in. pots, in which they may be allowed to flower. This plant is also very useful for furnishing beds in the conservatory.

Tritonia rosea. This slender and graceful species, although hardy in dry, warm situations, is very charming when grown in pots for the cool greenhouse. Dry corns may be purchased during autumn and winter. They should be potted early in the New Year, placing twelve corns in a 6 in. pot. They are best grown in a cold frame. *Royal Botanic Gardens, Kew.* J. COUTTS.

The "Everyman's" Patent Straining Wire.

One of the most useful labour-saving devices we have come across for some considerable time is made by the House and Garden Sundries Company, which manufactures the now well known "Everyman's" wall-clips and the very handy

Fig. 20.

Fig. 21.

using successive batches this plant may be had in flower for several months.

Dicentra eximia is a much smaller-growing plant than the above, only reaching a height of from 1 ft. to 18 in. It is, however, very graceful and is worth growing in shallow pans for the small unheated greenhouse.

Chrysanthemum Parthenium fl. pl.—Although a hardy border plant, this *Chrysanthemum* is very useful for conservatory decoration. Where grown for this purpose cuttings should now be inserted, the young shoots springing from the base of the plant being used for this purpose. Old plants may often be pulled to pieces with the young shoots already rooted. In this case they may be potted directly into small pots, afterwards standing them in a cold frame. They should be grown perfectly cool and air admitted at all times. Useful plants may be grown in 48-sized pots, but where larger specimens are required they should be grown on into 6 in. or 7 in. pots.

Polygonatum multiflorum (Solomon's Seal). This charming and graceful hardy plant is very useful for a supply of cut flower. It is equally useful for growing in pots for conservatory decoration. For this purpose strong rhizomes should now be placed in 7 in. or 8 in. pots. Where required in quantity for cutting purposes the rhizomes should be packed closely in boxes, standing them outdoors until such time as they are required for forcing. For this latter purpose a temperature of 50° to 55° is high enough.

Calcecephalus (Leucophyta) Brownii.—This charming silvery-leaved plant is as a rule only used for summer bedding. Well grown specimens, however, are very beautiful at this time for the greenhouse, being especially useful for grouping with other plants. It associates very well with

little seed-sower marketed under the same trade name. The new invention we have in mind consists in securely attaching, at regular 4½ in. or 6 in. intervals, to ordinary galvanised wire, "ends" of soft iron wire which are also galvanised. To "tie up" a row of Raspberries, once the special straining wires are secured, is a matter of moments only. One has just to slip the cane between the two ends of wire, give the latter a twist, and at once the cane is securely held. To release the cane ready for another season's growth is an equally rapid operation. Does not the wire, it may be asked, cut the Raspberry canes? It appears after exhaustive experiments to have no detrimental effects whatever. Of course the canes are usually fairly woody when first "tied" and are of only one year's duration in any case. The Loganberry, Hailsham Berry and various Brambles will at once come to mind as almost requiring this special wire, but for these rampant growers the double lines of wire shown in Fig. 21 are a great advantage, as the young growths may thus be secured apart from the fruiting canes. Even for Raspberries many gardeners now like the double training system, as more canes may thus be left to a plant. Black Currants when trained in the way set forth in last week's issue may also be secured very readily by this patent wire, and in their case the single row shown (with Raspberries secured) in Fig. 20 is most convenient.

THERKILDSEN, F.R.H.S., Kew Gardens, Southport.

Kniphofia comosa.—Some folks complain that there are too many "Red Hot Pokers" and that these are "too much alike," but they cannot apply these remarks to *Kniphofia comosa*, for it is perfectly distinct and very unusual. The only advantage of the plant is that the foliage is rather ragged; but, this defect being once recognized, it is easy to screen the base of the plant with something else, and then one has only to enjoy to the full the beauty of the flower-spikes. These are borne on tall, thin stems which very often produce a secondary spike branching from the main head and a little below it. The heads of flower are short and bottlebrush-like in shape, and the colour is so intense that they almost look as if they were alight. These flower-heads are always an immense attraction to the bees which literally swarm among the glowing blossoms. A very remarkable point about the flower-heads is that they reverse the ordinary manner of opening by expanding from the top downwards.

A Pretty Daisy.—There is a refinement and charm about that little Daisy of the Atlas Mountains known as *Bellis rotundifolia*, but its variety, *coarulescens*, is still more dainty and attractive. This plant makes flat, spreading rosettes much after the fashion of our common field Daisy, the spoon-shaped leaves, rather grey and downy, being scalloped at the margins. From these rosettes a succession of delightful flowers is maintained from spring to autumn, these being nearly rim across and having their yellow centres fringed with rays of a most fascinating shade of cool lilac-blue.

Awards of the General Bulb Growers' Society of Haarlem (Holland).—The Floral Committee have made the following awards during their sessions July and August, 1923:

First-class Certificates.—*Gladiolus Lilac Wonder*, soft pink-violet, with purple blotch; *G. Quo Vadis*, light salmon-pink with carmine stripes; *G. primulinus Psyche*, fiery orange red with velvet blotch; *G. primulinus Vinula*, clear carmine.

Awards of Merit.—*Gladiolus Circe*, mauve with dark centre and white border; *G. Herbstzauber*, salmon pink; *G. Imperator*, creamy white to ivory white, well formed spike, stamens white, pollen mauve; *G. Mr. C. P. Alkenade*, ivory white, compact spike, firm; *G. Red Star*, velvety red with brown shading, compact spike, firm; *G. Veilchenblau*, very fine mauve with clear centre; *G. nanus King of Spain*, light scarlet with small white spots which have a purple border; *G. primulinus grandiflorus Flaming Sword*, clear vermilion with scarlet stripes; *G. primulinus Rosaura*, pink with vermilion centre; *G. primulinus Wilhelmina Regina*, soft apricot colour, small delicate flowers; *Lilium Pseudotigrinum*, orange with purple spots.

Distribution of Surplus Bedding Plants.—The surplus bedding plants at the London County Council Parks will be distributed to the public between the hours of 9 a.m. and 11 a.m. on Saturday, October 20, 1923. Persons desiring to participate in the distribution should make personal application to the officer-in-charge at the various parks. Plants will not be handed to children under the age of fourteen unless they present a note from their parents or teachers.

FORTHCOMING EVENTS.

October 25.—Royal Botanic Society's Meeting.
—Wargrave and District Gardeners' Society's Meeting.

NAMES OF PLANTS.—X. Y. Z., Birmingham.—1, *Cynoglossum* sp.; 2, *Amherstia martinica* seedling; 3, *Clonatis Nellie Moser*; 4 and 5, both forms of *Sodium Telephium*.—M. G.—1, *Carex brunnea variegata*; 2, *Cupressus pisifera* var. *squarrosa*; 3, *Pteris longifolia*; 4, *Pteris semipinnata*; 5, *Cornus albus*.

The World is made of—

ONE big reason why Kit is indispensable to gardeners is that the world is made of dirt. Kit, the rapid action hand-soap, can dig out of the pores of the hand any dirt that can get ground into them. Ordinary dirt it laughs at; paint and tar it can shift with ease; oil and grease it can banish at the first rub.

You'll notice that Kit leaves the hands feeling clean, as well as looking clean; that's because Kit has worked deeper than ordinary soaps can.

6d PER TIN.

SITUATION WANTED.

GARDENER (Head Working) experienced inside and out. Fruit, Flower, Vegetable and Herbaceous Borders. Age 36, married, no family, highest refs.—W. HALL, 19, Grange Park Road, Leyton, E.10.

NEW SPRAYING MACHINES LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete without a Sprayer, in fact a Sprayer is absolutely essential to obtain best results. During the War we supplied a considerable number of our well known Four Oaks Knapsack Sprayers—Rubber Diaphragm type—to the Government, and we have just re-purchased a small quantity back again, which have never been used. They are made of copper but painted Service grey colour. They have various special additions to the ordinary machines, and the price to-day would be £5 each. We guarantee them to be in perfect working order as new. We will send one machine carefully packed, carriage paid, on receipt of 50/-, but cash must accompany all orders. We would supply 2 machines for 90/-, carriage paid.

Please mention this Paper when ordering.

giving full particulars and testimonials
sent on receipt of postcard.

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

Cash Prices (including bags): Small (about 1 bushel), 3/-; Large (about 4 bushels), 7/-; 5 Large, 33/9; 10 Large, 65/-; 20 Large, 120/-.

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond.

MIXED DAFFODILS AND NARCISSI for naturalising, 20/- thousand. Barrii Cospius, 9/-; Emperor, Empress, Grand Monarque, Soleil d'Or, all 12/-; Scilly White, 15/-; Princeps, 6/-, all per hundred. Iris stylosa, 50/- per hundred. Packing free. Carriage forward, cash with order.—**TREWINE, Portscatho, Cornwall.**

ROCK GARDEN PLANTS SPECIALITY.—List free.—**TERRY LEE, F.R.H.S.,** 12, Morden Road, Stechford, Birmingham.

GLASSHOUSES.—**CARTER & HOWARD,** Raynes Park, S.W.20. Phone: Wimbledon 2377.

PRIOR'S CHAMPION COLCHESTER ROSES, Carnations, Dahlias, Gladioli, Fruit Trees, etc. Catalogue containing cheap Collections, free.—**D. PRIOR AND SON, LIMITED,** Champion Rose Growers, Colchester.

STRIKING NEW PERENNIAL VERBASCUMS.—"Cotswold Queen"—Very beautiful crushed strawberry, each 5/-; "Cotswold Beauty"—Deep biscuit, shaded purple, each 3/6; "Cotswold Gem"—Light broozy yellow, purple shadings, each 3/6.

DOUBLE WHITE ROCKET (Hesperis Matronalis Alba Plena), extra fine stock of this sweet-smelling favourite. Strong plants, 3 for 2/6, 12 for 9/-, 100 for 55/-, carriage paid for cash with order.—**R. TUCKER & SONS,** Brookside Nurseries, Headington, Oxford.

RARE ALPINE & ROCK PLANTS, a few selected from our enormous collection:—*Androsace pyrenaica*, 1/6; *Anemone Vernalis*, 1/-; *Dianthus alpinus* and *albus*, 1/-; *Iris gracillipes*, 1/6; *Saxifraga Burseriana sulphurea*, 1/6; *Campanula pseudo-Rainieri*, 1/-; *C. Miranda*, 1/-; *Æthionema pulchellum*, 1/-; *Arenaria balearica*, 6d.—**R. TUCKER & SONS.**

LISSADELL.—A few really good Rock Garden Plants:—*Campanula W. H. Paine*, *Dianthus casius grandiflorus*, *D. neglectus*, *Gypsophila fransisii*, *Hypericum reptans*, *Iberis axatilis*, *Phlox Vivid*, *Saxifraga lantoscana* Lissadell, *S. omifolia*, *Viola gracilis*, all 9d. each; postage extra. One each of the lot for 7/6, post free. Cash with order.—**MANAHER, Lissadell, Sligo.**

BIRDS' BATHS, GARDEN VASES, SUN-DIALS, NESTING BOXES. Catalogue (No. 4) free.—**JOORTON, 60, Buckingham Palace Road, S.W.**

SWEET PEAS AND HOW TO EXCEL WITH THEM. By HORACE WRIGHT, 9d. net, by post 11d. published at the Offices of "COUNTRY LIFE," LIMITED, 20, Avistock Street, Covent Garden, W.C.2.

DOWNER'S NEW LUPINS. Giant Stride in evolution. Marvellous colours. 60 seeds, 6/-.—**DOWNER** (Sept. 2), Drayton Manor Nurseries, Chichester.

AMES GRAY, LTD., Builders of Conservatories, Greenhouses, etc., and Heating Engineers, Danvers Street, Chelsea, London, S.W.3. Wire: Gray, Kensington 90. Telephone: Kensington 90 and 91.

BARR'S GOLD MEDAL DAFFODILS.—The finest sorts for Pots, Bowls, Exhibition, Flower Borders and to Naturalise. Also many New Seedling Varieties, offered for the first time. Descriptive Catalogue free.

BARR'S HYACINTHS, TULIPS, LILIES, CROCUSES, IRISES, etc., for pots and bedding. Finest quality. Descriptive Catalogue, with special directions for the culture of Bulbs in Bowls, free.—**BARR AND SONS, 11, 12 and 13, King Street, Covent Garden, London, W.C.2.**

THE DOUGLAS CLOVES.—Our wonderful new strain of Hardy Border Clove Carnations again won the Large Silver Cup at the R.H.S. at the Great Chelsea Show, June, 1923. We have now won more Awards of Merit of Royal Horticultural Society for Carnations than any other two firms together. Rigid stems, perfect calyx, glorious scent. New plant list.—**DOUGLAS, Edenside, Bookham.**

LOBELIA "HUNTSMAN."

—The finest of the scarlet Cardinal Flowers. New Daisy Hill Brooms in pots. Lists free.—**T. SMITH, Daisy Hill Nursery, Newry.**

GREENHOUSE PAINTING AND GLAZING.

—"Vitrolite," superior to White Lead Paint, 18/6 per gallon, cans extra. "Plastine," the Imperishable Putty, 32/- per cwt., kegs extra; 7lb. tins, 4/3 post free; 14lb. tins, 5/6 each, carriage extra, tins free.—Full particulars from **W. CARSON AND SONS, Grove Works, Battersea.**

ALLENS' ROSES

Avoid further failures by replacing with extra Hardy Trees grown on our East Coast Rose Grounds.

Send a card to-day for our Illustrated Catalogue.

ALL LATEST VARIETIES AT REASONABLE PRICES.

DON'T WASTE TIME AND MONEY ON APPARENTLY CHEAP FOREIGN TREES.

All trees **GUARANTEED**:—True to name, Home Grown and delivered in perfect condition.

A. J. & C. ALLEN, Bowthorpe Road, Norwich.

ALLEN'S
NORWICH

Notes from Maidstone.

CHERRIES.

It is not generally recognised that the colder garden walls will grow the Sweet Cherries as well as the universal Morello. We should recommend Governor Wood, Bigarreus Kentish and Napoleon, and in the Black Cherries, Early Rivers, Schrecken Bigarreau, Waterloo and Tradescant's Heart, a selection which covers the whole range of the Cherry season. We can supply good Fan Trained Trees of these at 15/- each, or smaller at 10/6.

Established 1796.

George Bunyard & Co., Ltd.,
The Royal Nurseries,
Maidstone.

CHOICE PERENNIALS FOR PRESENT PLANTING.

Delphinium, prize strain, two year old roots, 4/6. Carnation Baby Castle, the best salmon, very free, 4/6. Gum Lady Stratheden, splendid novelty, the yellow counterpart of Mrs. Bradshaw, 7/6. Montbretia Croesus, huge pure yellow, 1/6. Pinks Mrs. Sinkins, large clumps, 3/-. Allwoodii Joan, the best of all, 5/-. Cheiranthus Allionii (Siberian Wallflower), 2/6. Coreopsis, 3/6. Aquilegia, strong, 4/-. Gypsophila paniculata, 4/6. Polyanthus, giant hybrids, 2/6. Primula japonica and pulverulenta, 5/-. Rudbeckia purpurea, rich purple, 3/6. 5/-. Papaver Gr. Bramblebury, 6ft. high, immense brilliant scarlet flowers, unrivalled as a landscape plant, first time offered, 10/-. All per dozen. 10/- orders carriage paid.

CATALOGUES ON APPLICATION.

Bramblebury Nurseries, BUDE, Cornwall.

Do YOU know PARSONS'

WORCESTER BERRY?

If not, you have yet to learn of one of the most useful berries in cultivation:

and WHY?

It has **proved its worth** as a decided marvel in berry-bearing fruits, viz.:

As a Cropper.

As a Jam or Jelly Fruit, or for Tarts.

As a resister of Big Bud (or Mite) and Mildew.

Owing to heavy demands I have only a limited quantity, but offer, as far as my stock will permit, as follows:

Bushes or Single Cordons ..	2/6 to 3/- each
Extra Strong Fruiting Bushes..	3/6 to 5/- each
Double and Treble Cordons or Fan Trained, for Walls, Trellis, etc., Extra Strong Fruiting ..	3/6 to 5/- each

Packing and Postage extra, viz.:

1 plant, 9d.; 2 do., 1/-; 3 do., 1/3; 4 do., 1/6; 6 or more, carriage paid.

It has attracted enormous attention when exhibited at Shrewsbury, Harrogate, Glasgow and Edinburgh Shows, and the opinion of some hundreds who tasted it was "a delicious fruit."

If you have not seen above, ask for a copy of my New Fruit List FREE, with Coloured Plate of my Berry, Press Extracts, and Testimonials.

My List includes ALL THE BEST in APPLES, PEARS, PLUMS, etc., and my Worcester Grown FIBROUS-ROOTED Trees may be relied upon for BEST RESULTS and QUICK RETURNS.

EDWARD J. PARSONS, F.R.H.S., Fruit Specialist,
BARBOURNE NURSERIES, WORCESTER.

No. 2710.—VOL. LXXXVII.]

[OCTOBER 27, 1923.]

AUTUMN - FLOWERING CROCUSES

THE Crocus family consists of nearly a hundred species, although Maw in his monograph only gives figures of sixty-seven kinds. They are chiefly found in the Mediterranean region of Europe, but extend into Asia Minor, the Caucasus and Central Asia. The flowering of the various species extends over the greater part of the year, with the larger number in bloom in spring, nearly as many in the autumn, linked up by others that flower in winter. The autumn-flowering Crocuses are invaluable for giving colour at a season of the year when the majority of plants have passed out of bloom. Some of the more easily grown kinds are well adapted for naturalising in grass, like *C. speciosus*, a mass of which in flower makes an effective picture towards the end of September with the delicately veined purple-blue flowers set off by the orange-coloured anthers. When grown in a border it is an advantage to have a carpeting of some low-growing plant which does not grow too dense and which will shew off the flowers which appear before the leaves. Those which bloom in early autumn are the most useful, as at that time the weather is generally more favourable for their well-being, while those that flower later on in the autumn and winter have frost and rain to contend with. Successfully to grow the latter, it is necessary to plant them in a warm sunny border or cover with glass while in flower. The earliest of the autumn kinds, *C. Sharojani* and *C. valliscola*, flower in August, followed by the handsome *C. speciosus* and several others in September and October.

The culture of the Crocus is very simple, and choice of soil is not, of great advantage. They can all be grown quite easily in a light sandy loam,

any light garden soil suiting the corms. All the species in this climate enjoy the open sunshine, but they will flourish fairly well in open woodland where the grass is thin and the trees deciduous. Most Crocuses in a wild state grow among dwarf scrubby plants, through which the flowers appear, and which give protection to the shallow planted corms in winter. The corms should be planted as early as possible to allow for the formation of roots before the flowers are produced, and autumn-flowering Crocuses should be in the ground in July. They should not be planted deeply, some growers barely covering the corms with soil, but about 2 ins. below the surface in light soil is a suitable depth to plant. In making a selection perhaps the four best and strongest, as well as free-flowering kinds, would be *C. speciosus*, *C. zonatus*, *C. longiflorus* and *C. medius*. Besides these are many others of great beauty which are given below in alphabetical order.

C. ASTURICUS.—This is a very showy, free-flowering species from the Asturian Mountains,

with flowers varying in colour from dark purple to lilac and pale mauve. A white variety of this is figured in Maw's monograph of the genus, but is not now apparently in cultivation. Somewhat short in stature, it is of sturdy habit, and is not so easily broken down by rain as some of the others. It is September flowering.

C. BORYI.—From the Ionian Isles, this has creamy white flowers, sometimes veined with purple, while the base is yellow and the scarlet stigma entire. It flowers in October.

C. CAMBESSEDESI.—A rare miniature species from the Balearic Isles, it is not common in gardens. The inner segments of the flower are white with a violet base, while the outer ones are yellowish white and feathered with crimson. November.

C. CANCELLATUS.—A species with a somewhat wide natural distribution from Greece to Northern Persia. With such a wide range it follows that there are several varieties, that of the type having white flowers with a purple base. The variety

cilicicus from Asia Minor has lilac flowers veined with purple, while the variety *maziaricus* has white flowers with an orange-throat. All flower freely in a warm sunny place in October.

C. CASPIUS.—One of the finest white-flowered autumn Crocuses, and closely allied to the better-known *C. Boryi*. It is a comparatively recent introduction from the Caspian region, and flowers in October and November, often keeping on till February. The variety *lilacinus* has the outer segments suffused with lilac.

C. CLUSII.—Comes from Portugal, and has pale violet flowers in October. It is very tree-flowering and hardy.

C. HADRIANICUS.—A native of the Ionian Isles with pure white flowers very freely

A BEAUTIFUL AUTUMN-FLOWERING CROCUS, *C. SPECIOSUS ALBUS*.

C. FLAVUS.—This species is a native of the Caucasus. It is a very variable species, the flowers being of various shades of yellow to that pencilled at the tips with blue lines, and another variety with a good violet base. This species is best grown in light soil.

C. IRIDATUS.—This species is so named from the shape of the flower to that of an Iris. The outer segments are rich purple, while all inner ones are pale lilac. It is a native of Bonat and Transylvania, and grows best in shady places, it being generally found growing among low bushes. A group in flower is charming in September and October.

C. FLAVIGATUS.—From the Cyclades, this is a free-flowering kind coming into bloom in October. The flowers vary from white to lilac, the outer segments being either self-coloured but or rather red and suffused with rich purple.

C. LONGIFLORUS.—A charming free-flowering plant from Southern Italy with soft rose-coloured fragrant flowers in October. This is one of the best of the autumn-flowering kinds and should find a place in every garden. It comes into flower after *C. speciosus* and lasts well on into November. It is very variable in colouring, some forms being externally veined with purple, one being called var. *Wilhelm*.

C. MARATHONISUS (syn. *C. niveus*).—A native of Greece, closely allied to *C. Boryi*, this is a very handsome white-flowered kind with flowers quite high in November. It is best grown in a frame or very sheltered sunny position.

C. MEDIUS. This species is one of the best with broad and overlapping segments forming a cup-like flower. The flowers exceed 1 cm. in height, and are over 1 cm. in diameter when fully expanded. The colour is a rich mauve-purple with little veining, and the stigma forms a cluster of rich scarlet filaments that droop gracefully and are very attractive. It is found in Northern Italy, but, unfortunately, it does not increase so readily as some of the other Crocuses, therefore it is not so plentiful as could be wished. There is also a pale rosy lilac form in cultivation. It flowers in October.

C. NUDIFLORUS.—September is the flowering-time of the Pyrenean *C. nudiflorus*, with large, tall-growing flowers of a clear purple. This species is naturalised in some of the Midland counties of England, and is remarkable for its curious habit of sending out stolon-like growths which form new corms at a distance from the parent plant. It needs a moister position than many others and does well among *Anemone sylvestris*.

C. OCHROLEUCUS is a small, creamy white-flowered species from the Lebanon with a bright orange base. It is not so hardy as most, and requires a warm, well sheltered position in light sandy soil. November.

C. PULCHELLUS.—This is a useful species for planting in sunny situations in short turf. Its flowers much resemble those of the better-known *C. zonatus*, with the same cup-like shape, but the segments are broader and the stigma very little divided. The segments are lavender blue in colour, with a richer veining of purple. This free-flowering Crocus is found wild abundantly in the heathy thickets bordering the Bosphorus and other parts of Eastern Europe. It seeds itself freely, and soon forms large groups which produce quantities of flowers in September.

C. SCHIMMELI. In most gardens this is a disappointing plant, not flowering so freely as it might. The flowers are pale purple in colour with deeper veining. It is a native of Langiers, and forms large corms and large tufts of grassy leaves in October.

C. SATIVUS. Like the above, this is not a free-flowering plant in this country. It also forms large corms and tufts of grassy foliage. A native

A GOOD FORM OF *CROCUS LONGIFLORUS*.

of Eastern Europe and Western Asia, it is a very variable species, and there are many named varieties. The type has bright lilac flowers with a purple base, suffused with purple veins. Var. *Pallasii* is purple with a golden base; var. *Thomasii* is purple; var. *Curtwrightianus* has purple or white flowers; while var. *Elwesii* has large white flowers. The last named has proved more free-flowering than some of the others. November. It is widely cultivated for producing saffron.

C. SHARONJANI.—This is a very rare species from the Caucasus, and is probably not now in cultivation. It is remarkable for producing its rich orange yellow flowers in August, being one of the first Crocuses in flower.

C. SPECIOSUS.—In many respects this is the most useful of all the autumn-flowering Crocuses, and is admirably adapted for naturalising in grassland where the grass does not get too coarse.

Here it multiplies freely, numerous little corms forming at the base of the parent one. Hence it is difficult to eradicate when well established. For the partly shaded fern border it is very useful when the plants are not too close together. A large group of this in flower at the beginning of September makes a very attractive picture in such a position. The flowers are large, open wide during sunshine, and vary somewhat in shape and colour. In the typical forms the colour may be described as a bluish violet, and the segments are prettily veined with dark purple. In a wild state this species has a wide distribution, being found in Transylvania, Asia Minor, the Caucasus and Northern Persia, among other places. *C. s.* var. *Aitchisonii* is a fine large variety from Persia with larger and lighter-coloured flowers. There is also a beautiful white-flowered variety. All are very free-flowering, and self-sown seedlings come up freely.

PERHAPS THE MOST USEFUL OF AUTUMN-FLOWERING CROCUSES, *C. SPECIOSUS*.

C. TOURNEFORTII.—This native of Greece requires a warm, sheltered position, but even then it does not flower freely. It has large corns, tufts of grassy leaves and delicate rosy lilac flowers in October.

C. VALLICOLA, from the mountains of Armenia, has the segments feathered with rosy pink. It flowers in August. It is a rare plant and probably not at present in cultivation.

C. ZONATUS.—A beautiful, free-flowering little plant from the mountains of Cilicia, it is remarkable for having a flattened, irregular-shaped corn, which distinguishes it from all others. It will thrive in grassland or border, and reproduces itself very freely from self-sown seed. The flowers are rosy lilac in colour, and have a bright orange

zone near the base of the segments. It can be distinguished from *C. pulchellus* by the much-divided, pale yellow stigma.

After these come the winter-flowering species, of which one of the two best is *C. hyemalis* from Palestine, which comes into bloom in December. It should be grown in a frame or in pots for the alpine house. The typical form has white flowers, the outer segments of which are veined or spotted with purple on the outside. *C. h. var. Foxii* has black anthers, and is the commonest form of this species in cultivation. *C. vitellinus* is a native of Asia Minor, and bears handsome orange-coloured flowers in early January. Of this there is a variety with rich brown markings on the outer segments, *C. v. var. graveolens*. W. J.

TREES & SHRUBS FROM CUTTINGS

AMONG the several phases of propagation by seeds, cuttings, layering, grafting and budding, that of increase by cuttings is perhaps the most important, and certainly provides abundant openings for the skill and energy of the propagator. To borrow a popular term, one may truthfully say there are one hundred and one ways of propagating plants by cuttings, ranging from the abundant heat of the tropical propagating cases to the open border where Poplars, Willows, etc., root freely. There is an equally wide variation in the best type of cutting to use at different seasons, from the soft, tender young shoot to the hard wood of the Willow and Tamarisk. While there is a "best" season to select for propagating most trees and shrubs by cuttings, the work is going on more or less throughout the year, with a busy time from June to November.

There are very few trees and shrubs which cannot, in some way or another, be induced to root from cuttings. Here it is that the resourceful individual stands to score as a propagator. There is, no doubt, an element of truth in the statement that the most successful propagators are born, not made; but the man with imagination usually "gets there" at the finish. While very many trees and shrubs root readily from cuttings by several different methods, there are three main considerations in dealing with the type of cutting and the method of treatment.

The best season to insert the cuttings is important, and on this question the propagating notebook must be very accurately kept, recording successes and failures at different seasons. On this item hinges consideration number two, the best type of cutting: whether soft young shoots, half-ripened wood, or the mature growths of the year give the best results. There will be a little variation in the actual date from year to year, according to the season, whether it be early or late. The year 1923, as far as cuttings from the open air were concerned, was unusually late; on the other hand, the hot summer of 1921 matured the shoots in advance of the average dates. The third great item in stringing cuttings is the method of rooting, whether under glass or in the open air, and if under glass the alternatives of bottom heat, just a little artificial heat, intensive heat and moisture in a sun frame, or a cold frame, handlight or cloches. The need of all these varying times and conditions is found in practice in that the widely different growths of trees and shrubs require varying methods of treatment.

Since sand has come so much to the fore as a rooting medium the careful preparation of composts for different types of plants has declined in importance. The most desirable consideration is that the soil should be freely porous in order

that the surplus moisture may drain readily away. This explains the fact that cuttings inserted

FOR PROPAGATING TREES AND SHRUBS.

round the side of a pot almost invariably root before those in the middle when soil is used. Cuttings inserted in pure sand must not be left long when rooted, as the material contains very little plant food. The first soil used for the initial potting from the sand should contain plenty of coarse grit. Unless this precaution is taken it is found that the roots of some cuttings do not take freely to the soil straight from the porous sand.

With most cuttings it may be taken as a fairly safe guide that the softer the growths (that is, generally, the earlier in the season) the more heat may be safely given to root the cuttings. There are, of course, many exceptions, but it works out something like this: A fair amount of heat during June and early July, a close frame with moderate heat in July and August, the cold frame (with handlights) and cloches during August and September, finishing up with mature growths in the open, and under cloches and handlights, from October to December.

In dealing with extensive collections of trees and shrubs, a propagating house somewhat similar to the one illustrated is very desirable, if not, indeed, a necessity. There are hot-water pipes under the propagating cases on one side. Several of these contain sand beds, others have the pots of cuttings plunged in fibre. In other cases, which are ventilated as required, the rooted cuttings are put in small pots, gradually hardened off, and moved to the benches on the other side. On the benches also, cuttings which do not require bottom heat can be rooted in handlights and under bell-glasses.

Some considerable time is gained in rooting deciduous shrubs in heat when large batches are required. I have in mind numbers running into hundreds of Forsythias, Philadelphuses, Diervillas, Aucubas, etc., rooted during June. The young shoots rooted in a fortnight, were potted off singly, made good growth, and were planted outside, when nice little bushy plants, in September. In the ordinary way at this season there would be the intention to prepare the ground and insert the cuttings on a border outside.

Numbers of uncommon shrubs and those not easy to root outside, can be successfully increased by cuttings with artificial heat or on a hot-bed. Soft young shoots of *Prunus subhirtella* and *P. pilosiuscula* root readily in heat during June and early July. This we also find the best time to root the deciduous *Rhododendron* (Azalea) cuttings. The important point is to induce growth and free rooting when the shoots are young. If allowed to get fairly firm, the cuttings, when inserted in late August, mostly form a "callus" and hang about through the winter, many

never getting beyond this stage, falling a prey to damp during the dull dark days of winter. Named varieties of the Ghent and nobis Azaleas, and especially the occidentalis hybrids, can be readily increased by cuttings made of the half-ripe young shoots during July.

August is a busy time for the propagator of hardy shrubs. Cuttings are still being inserted in the heated frame, but it is the cold frame and cloches which will receive most attention. There

the Heath and the Cistus, to name a few important hardy shrubs for cold frames. This continues through September, and then in October and November, the cutting borders outside are filled with Roses, Poplars, Willows, Tamarix, Sambucus, Ribes, etc., selecting the young woody shoots.

With new shrubs and those about which any difficulties are encountered, make a start with soft cuttings in heat in June; then, as the season advances, try half-ripe, firm and mature shoots under varying conditions.

The sun-frame, the idea of which I believe originally came from France, depends, as the name suggests, for its heat upon the sun. Placed in an open position facing south, a bed of sand or sandy soil is made up to within about 1 ft. of the glass with ample drainage beneath. The cuttings, after insertion, are never shaded, but water is freely given half a dozen or more times on the hottest days. With the sun shining full on the glass it will be readily understood how hot the interior becomes. By this means many cuttings root very quickly, among them plants which do not strike freely under ordinary treatment. Sometimes a second frame is placed inside the first, with even better results; the idea being that, while the heat and moisture are intensified, the sun does not shine so directly upon the cuttings.

Considerable care should be exercised in selecting the right type of growth for cuttings. There is usually the choice of a happy medium between coarse or very strong shoots and those which are too thin and wiry. As a rule, healthy side growths make the most satisfactory cuttings. In some instances, those with a thin base or "heel" of the previous year's wood give the best results. Others root freely when cut off just below a node (joint); while a few, notably the Clematises, root freely along the internodes.

The length of the growths suitable for cuttings is a very variable item. Heaths run, to 1½ ins. long are among the shortest; with Willows and Poplars at the other extreme, up to 2 ft. or more in length. With the cold frame and outdoor cuttings the wood must be moderately firm; sappy shoots and tops are very liable to flag, the period of rooting being longer and the conditions more airy than in a heated frame.

The depth to insert the cuttings in the sand or soil is more important in the open air than under glass. Firm cuttings 1 ft. long should be inserted up to half their length outside. Under glass, with shorter cuttings, one-quarter to one-third of the shoot is a good average to take as a guide.

Autumn is the most important period for the propagator of hardy trees and shrubs from cuttings. The cold frame, cloches and handlights, under the shelter of a west wall, and the cutting beds on a west border or in the open, each and all receive their quota of the cuttings which are found to root best under the differing conditions. There is no excuse even for the reader with a small garden but no glass frame or handlight. A box with drainage and sandy soil can be used to root cuttings of many shrubs if the top be covered with a sheet of glass.

A. K.

FORTHCOMING EVENTS.

October 2. Royal Horticultural Society's Fortnightly Meeting (two days).

November 1. National Chrysanthemum Society's Annual Exhibition, to be held at the Royal Horticultural Society's Hall (two days). — United Horticultural Benefit and Provident Society's Festival Dinner, to be held at the Imperial Hotel, Russell Square, London, at 7 p.m. Tickets (Price 6s. 6d.) may be obtained from the secretary, Mr. A. C. Hill, 35, Alexandra Road, London, W.14.

DECIDUOUS RHODODENDRONS

The term Azalea as generally used refers to the deciduous species of the genus Rhododendron. It is a useful and distinctive name in the garden, but the botanical differences and similarities between the deciduous and evergreen species are so closely interwoven that it is found impossible to draw a hard and fast line.

THE opening of the planting season among deciduous shrubs seems a fitting time to discuss the value and beauty of many of the deciduous Rhododendrons in our gardens. In point of rich and brilliant colouring they easily occupy first place among hardy shrubs. Coupled with this gorgeous colouring in spring and early summer is the delightful fragrance of many sorts. This is particularly noticeable among the hybrids of *R. flavum* and *R. viscosum*; the mollis and sinensis varieties are by no means so powerfully fragrant as the Ghent varieties. The question of scent should receive at least equal consideration with that of colour, size and habit by the hybridist.

With many Azaleas there is a further period of striking beauty in autumn, the rich red, orange,

dryness at the roots, a liberal mulching of decaying leaves annually in spring is very desirable.

The deciduous Rhododendrons are readily raised from seeds. The Ghent and mollis Azaleas can also be raised in this way, the seedlings being very suitable for extensive woodland and park plantings. To reproduce the named sorts true to type increase must be by layering, cuttings or, as a last resource, grafting. The best time to insert cuttings is in summer, when the young shoots are becoming fairly firm (half-ripe) but not hard and woody. At this stage they will root in a close frame with a slight bottom heat.

While the question of shelter must receive attention when arranging the planting of the mollis hybrids because they flower rather early, the Ghent hybrids are excellent for lawn beds

A TYPICAL GHENT AZALEA IN FLOWER ON THE LEFT.

bronze and crimson colouring of the foliage being a conspicuous feature of the landscape where large groups are planted.

TRANSPLANTING.

I like the large-leaved evergreen Rhododendrons, the deciduous groups also have close masses of fibrous roots forming large balls of soil. With ordinary care there is practically no risk in transplanting the subjects of these notes. While planting may be done at any convenient time between November and March, the early part of this period is preferable in order that the balls of soil may be nicely settled in the new positions before the approach of the flowering season. The Azaleas thrive in any lime-free soil, either loam or peat. With the loam, in particular, plenty of good leaf-mould should be dug in when preparing the ground and planting the bushes. With such nicely rooted plants it is important to tread the soil firmly. Impatient is these plants are of

in the open. There is, however, much to be said in favour of shelter for all the Azaleas, because they favour a cool and rather moist rooting medium. This is more often obtained when there is shelter such as is provided when Azaleas are planted on the slopes of open woodland valleys.

Mulching has already been mentioned, but it is such an important cultural detail that no excuse is necessary for enlarging on the matter. For light soils in particular, a mulching of half-decayed leaves and old manure, such as that from a spent mushroom-bed or old hot-bed, is most helpful in keeping the roots cool and supplying nutriment.

It is very desirable to remove the seed-vessels as soon as the flowers of Azaleas fall. If this is overlooked, much of the nutriment which should go to promote healthy, vigorous young growths is taken up in the development of seeds. Some of the hybrids are sterile, but many produce good seeds. It is interesting work, raising a few seedlings from the best hybrids, for, although they

do not come true, many are beautiful in flower, and occasionally one produces flowers equal or even superior to those of the parents.

A few evergreen species, such as *RR. amoenum*, *indicum* and *obtusum*, formerly belonged to a section of Azaleas, but in these notes only the deciduous species and hybrids are brought under review.

R. CALENDULACEUM is a native of Eastern North America. Were this a new plant instead of a beautiful shrub cultivated in our gardens for more than a century, we should acclaim its beauty from the housetops. In point of size and gorgeous colours the species may be dwarfed by the hybrids, but all the same *R. calendulaceum* is a very valuable hardy flowering shrub. The flowering season is June, just when the wonderful colouring of the hybrids is on the wane. Rhododendron enthusiasts are now giving much more attention to the species, and the Monograph on Azaleas by Messrs. Wilson and Rehder has added fuel to the flame. The outcome is the growing of large numbers of seedlings from the wild American species, including *R. calendulaceum*. The colours in a wild state range from yellow to scarlet.

R. DILATATUM flowers in April, the purple unspotted blossoms being freely produced on the leafless twigs. It is a native of Japan. Mr. Wilson, in his recent Monograph, includes *R. dilatatum* and *R. rhombicum* as synonyms of *R. reticulatum*. As we grow them in gardens, they are distinct plants, *R. dilatatum* having larger flowers and being freer flowering, a more shapely bush and hardier. It also has only five stamens, while *R. rhombicum* has ten. The wild specimens shew many intermediate forms between these two, which influenced Mr. Wilson in making his determination. *R. dilatatum*, as seen at Kew, is, apart from its floral beauty, worthy of cultivation for its gorgeous autumn colouring of rich bronzy scarlet and red.

R. FLAVUM is the only Azalea found growing wild in Europe, being a native of Eastern Europe, the Caucasus and Asia Minor. It has been freely used in raising the present race of garden Azaleas; but there is still room for the species, with its

deliciously fragrant yellow flowers and richly coloured autumn foliage.

The mystery surrounding the two Eastern species, *R. molle* and *R. sinense*, has at last been unravelled by Mr. Wilson. The yellow-flowered species, *R. molle*, is a native of China and the one with orange red or flame red flowers is a common wild plant in Japan. For this Mr. Wilson prefers the name *R. japonicum*, the name *sinense* having been used for both plants.

R. NUDIFLORUM is the parent responsible for the pink colour in most of the garden Azaleas. It is a native of Eastern North America and was first introduced in 1734.

R. OCCIDENTALE was first introduced by William Lobb from California about 1850. The flowers are white or sometimes pink with a yellow blotch. In recent years this species has been used in the raising of a late-flowering race of garden Azaleas.

R. VASEYI is one of the hardiest Azaleas, being a native of Western North Carolina at from 3,000ft. to 5,000ft. elevation. It is one of the most beautiful Azaleas, producing quantities of pale pink blossoms in early May.

R. viscosum, the Swamp Honeysuckle, is a valuable late-flowering shrub. It is a native of Eastern North America, and was first introduced in 1734. The flowers are white or pink tinted, freely produced during late June and July. This species was one of the parents of the earlier hybrids, but with the introduction of the more showy *R. molle* and *R. sinense* it has declined in favour with the hybridist, despite its delicious fragrance and late-flowering qualities. The variety *glaucom* has distinct bluish grey leaves, blue-white beneath and white viscous tubular blossoms.

Other deciduous species include *R. Schlippenbachii*, a native of Manchuria and Korea, a very beautiful Azalea but which requires protection in spring, otherwise young growths and flowers suffer badly in most seasons from white frosts. The delicate rose pink blossoms are 3ins. to 3½ins. across. *R. quinquefolia* is a Japanese species flowering in April. There are forms with pale pink and white blossoms. *R. Rhodora* is a very

old garden plant, opening its rosy purple flowers in April.

Seeds of the following little-known American species were received a few years ago: *RR. arborescens*, *canescens*, *oblongifolium*, *prunifolium* and *roseum*. The last named has been confused with *R. nudiflorum*, but has the leaves pubescent beneath and deeper-coloured flowers, though this latter may not be a consistent character.

GARDEN HYBRIDS.

So much crossing and intercrossing has been done between the North American species *R. calendulaceum*, *R. nudiflorum*, *R. occidentale* and *R. viscosum*, the Chinese *R. molle* (syn. *R. sinense*, Sweet.), the Japanese *R. japonicum* (syn. *R. sinense*, Maximowicz.) and *R. flavum* of the Caucasus, Asia Minor and Eastern Europe, that it is difficult in many of the progeny to distinguish the parentage with any degree of certainty.

For general outdoor planting the most popular and beautiful race at the present time are the Ghent Azaleas. The original parents of this group are *R. calendulacea*, *R. flavum*, *R. viscosum* and *R. nudiflorum*. Records point to the birth of this race almost simultaneously between 1825 and 1830 in the Earl of Carnarvon's garden at Highclere, and in the garden of M. P. Mortier, a baker of Ghent. Almost a century later, from this small beginning, we have an enormous number of varieties in cultivation, providing during May a wealth of colour second to none in the wide field of hardy trees and shrubs. A selection of the best named sorts should include the following twelve: *Bouquet de Flore*, deep rose pink; *Coccinea speciosa*, orange scarlet; *Gloria Mundi*, salmon, flushed orange; *Hollandia*, yellow; *Ignia nova*, carmine; *Mme. Gustave Guilmont*, rose; *Nancy Waterer*, Indian yellow; *Queen Victoria*, magenta red; *Roi des Belges*, pink; *Unique*, saffron yellow; *William III.*, orange shaded rose; and *Sang de Gentbrugge*, crimson.

The race of free-flowering Azaleas obtained by crossing the Japanese *R. japonicum* and the Chinese *R. molle*, grown in nurseries as *Azalea mollis* - *sinensis*, is, if anything, richer in colour, and the flowers larger than the Ghent section,

THE APTLY NAMED RHODODENDRON NUDIFLORUM.

THE PINK-FLOWERED FORM OF RHODODENDRON OCCIDENTALE.

At the present time in advance of the Ghent Hybrid, the Azaleas are liable to damage by late frosts, and, what is even more important, are not so luxuriously fragrant, a feature of the Ghent, as obtained from the parents *R. viscosum* and *R. japonicum*. For early flowering under glass these hybrids are invaluable for decorative work and cutting. Here again there is such a wealth of named varieties it will suffice if only several of outstanding merit are mentioned: Anthony

Koster, golden yellow; Floradora, red; J. C. Van Thol, very red; Queen Alexandra, orange salmon; J. J. Seidel, salmon red, and Alphonse Lavallee, flame red.

There are also numerous double-flowered hybrid Azaleas, a feature of which is the lengthy period the blooms last in good condition on the bushes. A selection should include Bartholo Lazzari, orange yellow; Bijon de Gentbrugge, white, shaded lilac; Louise A. Van Houtte, red; Narcissiflora,

yellow; Raphael de Smet, white, flushed rosy lilac; and Rosetta, rose.

The crossing of *R. occidentale* and *R. japonicum* has given us a very useful set of late-flowering fragrant Azaleas. The ground colours are creamy white and blush or pinkish white with yellow and pink markings. In addition to being sold as seedling "occidentalis hybrids," a few have been named as follows: Exquisite, Graciosa, magnifica, superba and rosea. A. O.

SHRUBS, MICHAELMAS DAISIES AND FERNS AT VINCENT SQUARE

CHIEF among the many exhibits in the Hall was the large collection of hardy trees and shrubs shown by the Hon. Vicary Gibbs from Aldenham. The autumn colours of such as *Acer palmatum* and other Japanese Maples, *Rhus Cotinus* and *Amelanchier canadensis* were brilliant, but even these paled before the startling vividness of the foliage of the Poison Ivy (*Rhus Toxicodendron*). It is a pity that the sap of this shrub causes such unpleasant effects, as it would be of immense value for decorative purposes. It is, however, not to be recommended for general cultivation. Among the berried shrubs were long sprays of the Snowberry, with large fruits of snowy whiteness, *Berberis* in many species, ornamental Crabs and Cotoneasters, while the large hips of *Rosa Moyesii* were also very attractive. A large plant of the once fairly common *Erythrina Crista-galli* attracted a deal of attention on account of the unfamiliar large pea-shaped flowers of brilliant colour. A gold medal was a fitting reward for this fine collection.

Michaelmas Daisies seemed to overpower the remainder of the floral exhibits. These were to be seen in nearly every collection. The largest exhibit was a spectacular display by Mr. H. J. Jones, who arranged tall stands of distinct sorts against the wall and had ample baskets of sprays in front. The varieties with pink shades seemed to predominate, and these included Maggie Perry, Pink Perfection and Louvain. In the collection of Messrs. Waterer, Sons and Crisp a large stand of Brightest and Best was in good colour. Messrs. W. Cutbush and Sons had a lovely mass of Barr's Pink alongside Beauty of Ronsdorf and General Lemmon.

The newest Michaelmas Daisies were to be seen in a tall arrangement by Mr. E. Ballard. Mother of Pearl is a delightful tall variety with large flowers of pearly sheen. Beauty of Colwall is a good blue. Maid of Colwall is one of the best whites, and Little Pink Lady is certainly the best dwarf pink variety.

Other border flowers worthy of notice included *Polygonum atrosanguineum*, a much deeper coloured and freer-flowering *P. amplexicaule*, with a goodly collection of the almost hardy tall *Lobelia* shown by Messrs. B. Ladhams, Limited. *Salvia oliginosa* of beautiful almost gentian-blue colour was shown by Messrs. Waterer, Sons and Crisp. This is a comparatively rare but very useful all-weather border plant. Messrs. Bakers of Wolverhampton had a pretty little *Kniphofia* named Royal Standard.

One of the most interesting exhibits was Mr. Amos Perry's collection of 250 varieties of the Hart's Tongue Fern, and among them was to be found every possible variation and form of crestation. These are valuable for moist and half-shady places, and all the congested forms are

healthy, so that they become a pleasure in spite of their deformities.

Of totally different character was the collection of Ferns shown by Messrs. Barr and Sons. Although there seems to be an impression that these beautiful "Guernsey Lilies" are difficult to

who had generous vases and sprays of Verona, Perle Chatillonnaise, Normandy, Mrs. G. K. Thorpe, Dick Barnes and John McAlpine.

The generally favourable season has permitted growers to shew the gorgeous colourings of their Dahlias much longer than usual, and on the

BRILLIANT FRUITS OF BERBERIS BRACHYPODA GIBBSII.

grow, they really should present no difficulties to anyone possessing a sunny greenhouse. They are exceedingly beautiful and the flowers last quite a long time. The giant of the collection was Hera, which is of exceptionally robust habit, and yet the large pink flowers are very refined. The older variety, N. Fothergillii major, provided brilliant colour, while of the newer sorts Felicity, Prince of Orange and Dainty were very beautiful.

Beside his Cherries, Sir G. F. Hadden sent a group of Ros-way Crimson Pelargonium in full bloom to illustrate its value as a summer-bedding plant. Messrs. W. J. Godfrey and Son had many trusses of showy Zonal Pelargoniums, both single and double flowered, and also staged a quantity of their new Chrysanthemum Godfrey's Gem. Mr. W. F. Gullick sent a lovely lot of C Golden Almarante, his sport from the valued older variety. Golden Almarante is larger than the parent and is of good colour.

A large collection of border Chrysanthemums was set up by Messrs. Keith Luxford and Co.,

present occasion there were many charming displays. Mr. J. T. West had mostly the useful Miniature Peony-flowered varieties. Mr. J. B. Riding shewed a very large collection of all the types and made a beautiful group. His varieties Queen Mary, Mariame and Audrey were perfect. Mr. Charles Turner gave special prominence to the fascinating little Pompons, which are so charming in small vases.

Roses also are enjoying a longer autumn than usual, so that there were displays of delightful blooms by Messrs. F. Cant and Co., Mr. W. E. Chaplin, Mr. E. J. Hicks and the Rev. J. H. Pemberton. Among the many decorative Roses Emma Wright has been particularly successful this season; it was freely staged and in great beauty of colouring. America and David Lloyd George, two new pink Hybrid Tea varieties, together with W. F. Dreer of apricot tints, are also worthy of special mention.

There is no close season for greenhouse Carnations, and these flowers are present in quantity

and of consistently good quality no matter when the shows are held. Messrs. Allwood Brothers, Messrs. Stuart Low and Co., and Mr. C. Engemann all had their customary collections.

Sweet fresh Violets were staged in quantity by the Misses Allen-Brown and Mr. B. Pinney. That Violets may be pink seemed to astonish some of the visitors, who were fascinated by the bunches of *Cœur d'Alsace*.

While there were no vegetables proper, Messrs. Sutton and Sons set up a magnificent collection of saladings, of which most could be, and often are, used as vegetables. There were champion sticks of Celery of such valuable sorts as Solid White, Sutton's A 1 and Sulham Prize. Lettuce, both Cabbage and Cos, were equally well represented, and the heads of Matchless Cabbage Lettuce were well named, for it would be difficult to equal them. The Turnip-rooted Celeriac was exceedingly shapely and clean.

Mrs. O. M. Conrage, Crawley, sent a goodly collection of well grown Apples which included enviable dishes of such sorts as King of Tomkin's County, New Hawthornden, Winter Quarrenden, Lady Sudeley (of beautiful colour) and Parquet.

A fine assortment of Apples was staged by Mr. Edward Parsons, who also had a well fruited pot bush of his "Worcester Berry," which is stated to be a cross between Boskoop Giant Black Currant and Whinham's Industry Gooseberry. It bears fruits with the appearance of Black Currants and the flavour of Gooseberries, and may be grown either as a bush or as a climber, and we see no reason why it should not also be grown as a weeping standard, which would be novel and useful. His Apples included excellent dishes of Ribston Pippin, Worcester Pearmain, Bismarck and a dish of May Queen, a shapely Apple which certainly looked as though it would keep in condition until Midsummer.

A beautiful dish of Durendean Pears was included by Messrs. Daniel Brothers in a hardy fruit collection. Their dishes of such Apples as Charles Ross, King of the Pippins, Vicar of Beighton and Worcester Pearmain were splendidly coloured.

Major-General Sir G. F. Hadden sent from Berkhamsted three dishes of exceptionally fine Morello Cherries, which in some unaccountable manner seem to have escaped the eye of the Fruit Committee. The high quality of the fruits well deserved recognition. Mr. G. Trinder shewed fruiting branches of Golden Hornet, his fine autumn-fruited Raspberry.

NEW AND RARE PLANTS.

Aster Aldenham Pink.—This is a tall-growing Michaelmas Daisy of Novi Belgii habit with almost the foliage of the cordifolius section. It has good heads of bright pinkish flowers. Award of merit. Shewn by the Hon. Vicary Gibbs.

Aster October Dawn.—A tall Novi Belgii variety which bears large flowers made up of two or three rows of narrow ray florets which recurve at the tips and are of mauve colour. There seems to be a tendency just now to take into favour these thread-petalled varieties, but they are fair-weather flowers. Award of merit. Shewn by Mr. E. Ballard.

Berberis brachypoda Gibbsii. This is a stiff, erect-growing shrub, apparently of medium size. It is lightly furnished with smallish sage-green spatulate leaves and long, stiff, slender spines. The charm lies in the hanging bunches of berries, which are very freely borne and in disposal resemble those of the common Barberry. On the branches shewn there was a pleasant variation in colouring which ranged from a bright crimson through coral to rosy-flushed. We suspect that a little later

THE BEAUTIFUL NEW PINK DAHLIA SWEET.

all the shining berries will be a bright scarlet colour, when the shrub will be very showy. It appears to be deciduous. Award of merit. Shewn by the Hon. Vicary Gibbs.

Berberis Tom Thumbe.—In many ways this might be described as being a congested form of *B. Wilsonae*, for in its foliage and berries it suggests that beautiful species, though its habit is much more like that of *B. stenophylla* Irwinii. The little bush was said to be seven years old, and it was not more than 15ins. high by 18ins. wide. It should be a very useful shrub for the rock garden. Award of merit. Shewn by Mr. S. Morris.

Chrysanthemum Elsie.—An incurved Japanese variety of exhibition size. The long, broad,

substantial florets hang gracefully and recurve at the tips. It is of good yellow colour. Award of merit. Shewn by Mr. G. Carpenter.

Chrysanthemum Godfrey's Gem.—An exceedingly decorative single Chrysanthemum of Mensa size but not so formal in outline and with a very small disc. The pointed ray florets are gracefully disposed in two or three rows and are of golden buff shades lightly flushed with apricot. Award of merit. Shewn by Messrs. W. J. Godfrey and Son.

Dahlia Sweet.—An exceedingly decorative variety, belonging to the Miniature Paeony-flowered section (almost a Decorative Single). The round flowers are about 4ins. across and are of delightful soft pink shades of colour. Selected for trial at Wisley. Shewn by Mr. A. J. Cobb.

FOR THE ROCK GARDEN, BERBERIS TOM THUMBE.

MICHAELMAS DAISIES AT HOLLAND PARK HALL SHOW

Dahlia Attractive. This is a quite distinct novelty, and it used to be termed Anemone-flowered, which has always been more valued in France than in this country. Apparently there are now only a very few varieties in cultivation, and this above is a welcome addition to them, as they are exceedingly decorative and of especial value as cut flowers. This is a well formed, medium sized bloom with both the quills and ray florets a rich vinous crimson colour. The quills are very lightly tipped with gold. Selected for trial at Wisley. Shewn by Messrs. B. Ladhams, Limited.

Pyrus Aucuparia munda subarachnoidea.—This is a really good white-fruited Mountain Ash. In their opaque whiteness the berries resemble those of the Snowberry, but are smaller and the marks of the small calyx persist in a brownish shade of colour. Award of merit. Shewn by the Hon. Vicary Gibbs.

Scolopendrium vulgare muricatum fimbriatum capitatum.—This is a very handsome Hart's Tongue Fern. The long, shining, deep green fronds are gracefully undulated and lightly crested at the margins and prettily congested at the tips. The crenation is quite regular and very pleasing. Award of merit.

S. v. ramo-crispissimum conglomeratum.—This is an excellent example of the Parsley-leaved Hart's Tongue Fern. The compact plant was not more than 4 ins. high and was composed of curled, densely crested fronds. It is a very attractive variety and a perfectly healthy plant. Award of merit. Both Ferns were shewn by Mr. Amos Perry.

Cattleya Mrs. Gratrix.—A chaste and very beautiful bloom of more than medium size. The petals and widely expanded lip are beautifully crested, and are pure white with golden citron markings in the throat. First-class certificate. Shewn by Messrs. Sander and Co.

Cypripedium Albion, Bodnant variety.—A smallish Lady's Slipper Orchid. The well formed, shining white flower has a number of tiny rosy dots around the centre, like minute stars set in a milky sky. It is a very beautiful variety. First-class certificate. Shewn by Lady Aberconway.

THERE were plenty of them. In a way they dominated the Show, but their quiet colourings are never a match for the brighter flowers of the Roses and the Dahlias, both of which were staged in large numbers. Although there were so many (great exhibits like those of Mr. Ernest Ballard, Mr. H. J. Jones and Messrs. Dickson and Robinson being wholly composed of Michaelmas Daisies), the peculiar bright look which seems only to come when their blooms are developed in warm and favourable weather was wanting, so they did not as a whole look their best and, in consequence, the contrast with their gayer show-fellows was more marked than it might have been in a happier time. Then, again, the lateness of the season of this extraordinary freakish year prevented many varieties being brought to the Show. They were not out in flower, so willy-nilly they had to be left at home and by so much was each exhibit the poorer. Coming to details, readers of gardening papers may have noticed that one variety received an award of merit, viz., Mr. Ballard's white, Snowdrift. I should never have voted for it. I have very little doubt but that the vase of Snowdrift that was placed before the Floral Committee was immaculate in its whiteness and that the pretty flat flowers attracted the members. Before they cast their votes they may also have seen the two effective elongated humps—like those on the top of engines—which were prominent in the hall; but I could have taken them to a third where the skeleton in the cupboard was laid bare, and where the flowers were far from being pure white, being, as a visitor to my garden described them, "just like Dickey-daisies." Was, however, the award given to Snowdrift as a pure white? I believe there is such a thing as coloured snow! I am watching the Novi Belgii whites in my own garden very carefully, and at the moment of writing am wondering if, for one, Maid of Colwall is not a

better plant, but "nuf sed." In the course of a conversation with one of the heads of Messrs. Dickson and Robinson I was told that the firm were paying especial attention to roses and pinks, as they considered there were too many lavenders, mauves and purples on the market and that there was room for more of the rosy shades. I think so too. We can do with some pure pinks and roses without any blue in their composition. This bugbear is being got the better of in Roses, why not in Asters? Walkden's Pink, which was staged by this firm, attracted me very much on account of its pure colouring and the smart well groomed look of its individual flowers. It was found in a private garden near their nurseries. You may be sure I looked out for Pioneer. Of all the pinks in my garden it is the purest, and as the plant has such a light and graceful habit, it appeals to me for its form also. I found it in Mr. Ballard's group, but it looked very woe-begone, as if, in fact, the rose had come off the watering-pot as it passed over it. The plant is botanically interesting as being a cross between a cordifolius and a Novi Belgii, which is an "entirely new departure" in hybrid Michaelmas Daisies.

What a change-loving era this is! "Give us something new." No sooner do we get acclimatised to double flowers than raisers present us with a somewhat startling innovation in flowers with long, thin, spider's-leg-looking petals which are not bad in fair sunny weather, but which in wind become shock-headed and in rain very bedraggled and lumpy. Miss Eisle was one of the first, but we have now several others. The most effective are Grey Lady (real grey), Bee's Blush (pale pink) and Countess (rose). There are some flowers one takes to at once, but there are others which one has to get used to before one takes them to one's heart. These spidery fellows, with me, fall into the second category. Anyhow they were a feature of the Show and have come to stay. One loves the charm of perpetual youth in Peter Pan and we erect statues to his memory; but a flower which always looks as if it ought to open but never does is something totally different and no more pleasing than a half-baked Potato. This is how the half-opened Royal Blue struck me as I saw it in Mr. Ballard's group. I allow it is a very rich blue-purple, and that it may be deeper in tone than either the Rev. C. Nunn, Blue Gem or Little Boy Blue; but, to me, nothing can be an adequate compensation for what I can only look upon as a deformed development. We expect so much from Mr. H. J. Jones that we have got into the way of thinking that he must always be on the top of his form. He had a fine group and, having regard to the lateness of the season, I could readily believe him when he said he had stripped his nursery to provide sufficient material for his exhibit.

In the whole of the hall there was not a single vase of that splendid variety Climax. "Taking one consideration with another," I doubt if there is a better Aster. Mr. Jones displayed his favourite, Roddy, in great abundance. It is one of the ericoides section, and has pretty little pink flowers. In a way it reminded me of the well known Esther, but I imagine the plant is much taller. As I was looking at it a friend came up and propounded the question "Are these small-flowered try as satisfactory in gardens as the Novi Belgii section or the Amellus?" He evidently thought they were not, and I am half disposed to agree with him if one excepts the cordifolius group, Diana, Ideal, Photograph and

A WHITE-FRUITED MOUNTAIN ASH, PYRUS AUCCUPARIA MUNDA SUBARACHNOIDEA.

the rest. There was, in this circular group of big low-down blobs and greatly elongated engine-top humps, a vase of a singularly pure white with a clean-cut centre and regular ray florets. At present it is unnamed, but there must be possibilities about it or it would not have been there. Although I did not see Mr. Jones's very beautiful rich mauve Major Pat à Beckett in his own stand, there was a good bunch of it in that of Dickson and Robinson. I spotted it when I visited Mr. Jones's nursery last year, and I again noticed it at the Show this year before I got close enough to read the name. Some vases of the large pale Lavender doubtless caught more eyes than my own. It is one of the very best of all Michaelmas Daisies and is among the first to come into bloom. The individual flowers are large and very freely produced. They are all inclined to be more double than I, personally, would have them, but the plant is forgiven this venial pandering to present-day taste because of its general excellence. In more than one place there was a mass of Little Boy Blue. In colour it is not far removed from either Blue Gem or Rev. C. Nunn, but it is not nearly such a tall grower as either and would come in useful where Daisies on the dwarf side are wanted. A single vase of a *débutante*, October Dawn, nestled in a corner of the Colwall exhibit. I liked the pale purple of its shapely flowers, which reminded me in their build of those of the dwarf Amellus section. It, too, is a low-growing plant. I hope in some future notes to say more about it, when I see what happens to the plant which was sent me for trial. Anita Ballard seemed to be here, there and everywhere. Growers have evidently taken the advice tendered in Mr. Ballard's catalogue "Must be in every collection." It seemed to be so at this Show. Mr. Ballard will, I hope, forgive me when I say I can by no stretch of my imagination call it a "cornflower blue." *Mutatis mutandis*, how well the lines from "H.M.S. Pinafore" sum up innumerable flowers and their catalogue descriptions:

"Things are seldom what they seem,
Skim milk masquerades as cream."

I do not say that *Centaurea cyanea* under the unwonted conditions of an enervating and fattening durance vile may not have, in some instances, broken out into a pale heliotrope not far removed from the colour of Anita, nor would I for one moment suggest that Anita is not pretty. I was rather fascinated by the darker ends of the ray florets, which get paler as they near the central disc. Anita is a lively-looking young lady. This characteristic was shared, I noticed, by Maggie Perry. Francis Sands, which I noted as a flower of medium size—pale pinky mauve with a clean cut golden centre—was new to me. Lady Lloyd, Bluebell, Namur, Rev. C. Nunn and Winsome I find I have also jotted down in my notebook, but I have written enough. JOSEPH JACOB.

A SUN-LOVER

THAT deciduous shrub, *Peraphyllum ramosissimum*, belongs to the Rose family and is the only one of its genus. It inhabits dry hillsides in California and other parts of the Western United States, and is, more than all else, a lover of the sun. Its blossoms are pure white and about three-quarters of an inch wide, and they are followed by round, yellowish edible berries about half an inch in diameter. The foliage is of a greyish green hue, each leaf being 1 inch to 2 inches long and a quarter of an inch wide, differing from those of nearly all its allies in being without marginal teeth. The chief thing to remember in its cultivation is that it needs as sunny a position as possible. It can be increased by layers.

CORRESPONDENCE

HARDY CYCLAMENS IN THE MORAINE.

THE illustration shows a rather unusual way of growing the Hardy Cyclamens. Although common in rock gardens, it is seldom that they are seen in the moraine. *Cyclamen hederacifolium*

for them, and still they come and, what is more, to the same spots. By far the commonest at present is the putty-coloured and soft *Linax agrestis* and the beastly blackish *Arion hortensis*, which works as much below as above ground,

CYCLAMENS IN MORAINE.

in a wild state likes a "soil" composed of shattered rock of a calcareous nature, and rich, light vegetable mould. This fact suggested that a moraine made up of stone chips, old lime rubble and equal parts of well decayed turf and leaf-mould might make a good substitute for its natural environment. The corns were raised from seed and were planted in the moraine when three years old. When first planted they were well below the surface, but they have gradually risen, and the top of the tuber is now quite visible above ground. As a precaution against frost they get a top-dressing of small chips and light soil after the flowers are past. Autumn usually has little to shew in the way of flowers in the moraine, so the appearance of these dainty blossoms pushing up through the grey stone chips is very welcome. After the flowers are over the prettily marked leaves appear and remain in full beauty all the winter, in this way giving a double season of usefulness.—J. S. T.

SLUGS RAMPANT.

IT is perhaps not out of place to call attention to the activities of the slug pest at the present time. Slugs have been simply awful in the garden lately. To-night (October 6) I accounted for about 150 in a little over half an hour, partly attracted by a little pollard (hen meal) sprinkled on the ground in places where the more attractive (to slugs) and, of course, rarer plants are situate. I am afraid they got a good foothold during my holiday in July and early August, when the weather was only too favourable for propagation. It is a wonder to me how the smaller plants exist at all. In ten days during the past fortnight I have destroyed over 1,000 in the little time I could spare to look

and is most difficult to see. There has also been quite a number of the large slugs, including several of the large "spotted slug," *Linax maximus*, a slug 4 ins. to 6 ins. long, and some of which have been foraging around some recently obtained *Ranunculus glacialis*, which has, of course, completely disappeared, although protected by a zinc ring. Other large ones are the black *Arion* uted and a large brown one with an orange line along its ridged back known as *Amalia marginata*. They are on my "island" moraine, and have badly damaged the rosettes of several *Sedum sempervivoides*, eating into the surface of the fleshy leaves. I also notice quite a lot of the reddish "millipedes" which I have my doubts about. I have used the V.T.H. traps, but found they destroyed as many useful beetles (of course not the wireworm species) as slugs, so that I very rarely use them now. I am afraid the only sure way, although somewhat tedious, is persistent handwork at night with a lantern, and it is just as important or even more so to search for them in the winter months, when they are often very active. A good many can be collected in the daytime from winter Cabbage, Lettuce and other leaves in wet weather, but these do not look very well lying among one's choicer flowers.—T. A. L., *Middlestrough*.

THE PALE BLUE ITALIAN PERIWINKLE.

I BROUGHT this Periwinkle, *Vinca media*, from San Remo, where I found it growing very freely beside the small streams and ditches on the hillsides. With us it enjoys growing in the full sun, and flowers throughout the year. It has lately been making a very fine autumn display. The flowers are a little smaller than

to the "Pector Periwinkle, and the colour is pale sky blue and sometimes almost white. Periwinkles are very useful for covering bare ground, and their glossy evergreen foliage is always tidy and pleasant to look at, apart from the real beauty of the flowers. They also have the advantage apparently of being immune from the attacks of slugs, caterpillars and other insects. *Vinca melia* is also sometimes known as *V. acutiflora*.—RICH BICKLESTETH, *Cottingham*.

A GLADIOLUS SOCIETY?

THE Gladiolus appears to be coming more and more into favour, judging from the exhibits of it at the Royal Horticultural Society's meetings during this year. One or two new growers have put up not only some of the older varieties but also some newer ones of considerable merit. The competition for the Foremarke Cup was disappointing in the number of the exhibits staged. I understand that there were five entries, but only three came up before the judges, and the owner of one of these had not studied the "book of words" and clearly had not put up the best that he had. He confined himself mostly to seedlings. The failure of two of the entrants to toe the mark was, no doubt, due to the storm of the week before. The conditions for the cup competition, undoubtedly, are not easy for the small amateur to comply with, with hope of success. This is where the proposed Gladiolus Society might come in with a small schedule (with the permission of the R.H.S.) somewhat on the lines of the show held for Daffodils. It would enable those interested in this beautiful flower to compare not only the flowers of the same colour, but also those which bear the same name although not of the same colour. I understand that the opinion of some of the members of the old Gladiolus Society was that the schedules asked for too much from the amateur. Should a new society be formed, its first aim should be to encourage the small grower.—G.

APPLE THE HOUBLON.

AS one who puts in practice the old adage of "An Apple a day," etc., I am now in the enjoyment of the above Apple. It is now (October 13) in excellent form for eating, and in my opinion is most eminently useful as filling a gap between the earlier well flavoured Apples and Cox's Orange. Like a Pear, it has its "day," i.e., one must not eat it too soon nor too late, and fruits of it kept after the middle of November, though excellent in appearance as regards eating, are merely "whited sepulchres." To those who do not know The Houblon, it is a fruit with a distinct and characteristic flavour of its own—brisk, pleasant, aromatic and spicy—and, unlike certain aromatic Apples, it is very juicy. Its mellow and ruddy appearance, too, is attractive. If I were asked to outline a dessert Apple programme, I would begin with Gladstone, but would probably quickly put it on one side for Irish Peach, that most charmingly flavoured and juicy fruit that so few seem to grow, but is worthy of a place in every private orchard; then on to St. Eloiand, which is good, and gives us a foretaste of Cox's Orange, at any rate a scintillation of it; then our friend The Houblon. Cox's Orange then makes its entry, and I can find nothing to beat it, or even rival it, except American Mother at its best in a good season, and the season of "Mother" is so short that it is scarcely comparable with "Cox." I have now carried my Apple programme up to Christmas and, not being a greedy fellow, I hope, I suggest that one of your correspondents who appreciates eating Apples may like to carry on the sequence up to the end of the Apple season.—F. HERBERT CHAPMAN, *Rye*.

THALICTRUM DIPTEROCARPUM.

YOUR correspondent, Jock F. L. Cudmore, issue of September 22, page 4931, may be interested to know that *Thalictrum dipterocarpum* grows to a similar height in the grounds of the Right Hon. Lord Forteviot at Dupplin Castle, Perth. In 1921, the first year after planting, the greater number reached 7ft. and 8ft., and have done so each season since. To-day, September 24, the largest plant measured 8ft. 8ins. high and nearly 5ft. through its foliage. If not unusual, they are very desirable when well grown, remaining in flower for weeks. I may add that the plants here are in partial shade among Rhododendrons in newly made borders of stiff soil to which has been added liberal dressings of half-decayed leaves.—J. T. H., *Dupplin Gardens*.

THE DOUBLE LILAC PRIMROSE.

I WONDER why it is that the old Double Lilac Primrose is, comparatively speaking, so seldom seen nowadays in gardens. It is, at any

fertility of a flower until it has been afforded an opportunity to mature its ovary. Cultivation has disturbed the balance of Nature in many cases, and removed from essential organs the power to function properly. Knowing this, I decided to walk on the side of caution in offering advice upon the propagation of Strawberries. I decided to accept ripe fruit as the only indisputable evidence of fertility. Growers who propagate from such stock know at the time of propagation that it is likely to prove remunerative. Stock from which the blossom trusses have been removed may, and very likely will, be satisfactory, but because of the doubt I hesitated to commend it. One realises that the subject has many ramifications, and it would be extremely helpful if it could be investigated in a thoroughly scientific manner.—GEO. H. COPLEY.

The question is purely a practical one. Has anyone ever had difficulty, accidents excepted, in ripening fruits on Strawberry plants which produced bloom trusses and appeared healthy at flowering-time? Mr. Engleheart has, evidently,

THE BEAUTIFUL DOUBLE LILAC PRIMROSE.

rate in my experience, a vigorous grower and, it divided every second year, makes a fine show on the shady side of a shrubbery or on the north or west edges of a coppice. It used often to be grown, too, in the rock garden, but many people, I know, draw the line at double-flowered plants there. Its entirely pleasing colouring and its freedom to flower make it a very desirable plant and one which should not be allowed to die out like the beautiful old Pompadour, which I have not seen now for a number of years. Are there any plants of Pompadour still in existence? I wonder! There are several other interesting double forms, but none of them seems to be very largely cultivated at the present time. However, always excepting Pompadour, I think the Double Lilac quite the best.—N. H. P.

ABOUT STRAWBERRIES.

THE Editorial footnote to my letter upon Strawberry culture on page 506 raises a most interesting point. I cannot quite agree that the presence of blossom trusses is a certain sign of fertility. There is a doubt about the

struck no "snag" in taking the production of flowering trusses as evidence of fertility, and our limited experience confirms his. If any reader has evidence to the contrary, however, we should like to hear from him. [Ed.]

GEUM LADY STRATHEDEN.

AFTER growing this recently introduced plant for a considerable time and having tested it in various ways, I feel quite convinced that it is destined to take a high place among hardy plants either as a bedding plant, for grouping, or as an isolated specimen in the herbaceous border. The rich golden yellow double flowers are produced with lavish freedom throughout the whole season, lasting for a considerable time in good condition. It is also useful as a cut flower, the blossoms being carried on long, thinly branching stems which lend themselves to easy, graceful arrangement. When one states that it is an exact replica of the well known Geum Mrs. Bradshaw, except in colour, its usefulness will be readily recognised; and, like this well known favourite, it reproduces true from seeds.—ALBYN.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Onions.—The bulbs being already in store, it will be advisable to examine them at intervals—such work being undertaken when the weather is wet. Any examples showing signs of decay should be removed, and the sound specimens tied in small bunches and suspended from the roof of the shed. Cottagers often tie them to sticks and ropes, and the method has much to commend it.

Beetroots.—Roots from a late sowing should be lifted, taking care not to injure them in any way, or their cooking qualities will be impaired. Store them in a cool, dry shed, which should also be frost-proof.

Mint.—This herb is usually in demand the year round, and where the necessary glass accommodation is at hand it can be obtained at almost any date. Hot-beds are also useful for the production of fresh young shoots; when the heat is declining the roots should be laid thickly in the frame and lightly covered with leaf-soil. Roots may be placed in boxes if only a small quantity is needed, and they will grow freely in a temperature of 60° if kept moist.

Lettuce.—Plants in frames should receive all the light and air possible, and except during frosty weather the lights should be removed. Remove all weeds and stir the soil occasionally between the plants.

Jerusalem Artichokes.—When the stems have finished their season's growth they may be cut down to the ground level and burnt. Artichokes, like Parsnips and Salsify, may be left in the ground until needed for the kitchen, but, if at any time we are likely to experience frosty weather, a small quantity should be lifted and stored in a cool place. When digging Artichokes the work should be done thoroughly, picking out every tuber, however small, for, if anything is left, it will eventually grow and become a nuisance to future crops.

Winter Onions.—These will not be transplanted until the spring, but in the meantime the rows should be kept free from weeds. If neglected, they are soon overgrown, and it is difficult to remove large weeds without disturbing the plants.

The Flower Garden.

Roses.—Where it is intended to plant *Rosés* the order should be given and the ground prepared. In many instances, however, it will be merely filling up any blank places in existing beds, but where new positions are contemplated the ground should be prepared a few weeks before any planting is done. Rich loam of a retentive nature is best for Roses, but most soils can be made suitable. In light and sandy soils, incorporate some stiff loam and farmyard manure, while to those too heavy and chiefly clay, add decayed manure, sand, and ashes from the rubbish fire. Select an open situation well away from large trees, and if necessary the site should be drained. Dig the ground deeply and remember firm planting is essential.

Dahlias.—If the weather is favourable, these will continue to produce flowers, but directly the growth is injured by frosts the tubers may be dug up and placed in a frost-proof storehouse. Special varieties already marked for propagating purposes later on, should have their labels securely attached. The roots of *Salvia patens* and *Lobelia fulgens* may also be lifted and then arranged closely together in boxes, sprinkling some old potting soil between the roots and tubers. These may be stored in a cool greenhouse.

Lily of the Valley.—When the beds become crowded the plants should be carefully lifted and replanted. November is a suitable month to replant or make new beds. A partially shaded position should be chosen, and the crowns may be set out in lines 12 ins. apart and a few inches between each crown in the rows. If the soil is heavy, it can be improved by the addition of old potting soil and leaf-mould. Beds not disturbed may be afforded a light top-dressing of leaf-soil and short manure.

The Hardy Fruit Garden.

Wall Trees.—The pruning and tying in of fruit trees on walls should be proceeded with and, if possible, completed before the cold weather arrives. During congenial weather more progress is made. At this season the borders are often very wet, so, to prevent the soil from being puddled to any extent, we usually employ a few planks. If the leaves have fallen, the Morello

Cherries are dealt with first. The pruning of Peaches and Nectarines is a fairly simple operation if the grower remembers that fruit will be produced on the growth made this season. Cut out as much of the old wood as possible and retain new shoots which are well ripened. Maintain a well balanced tree, and do not overcrowd the growths. Before the trees are tied give them a thorough dressing with an insecticide, such as Gishurst Compound. When tying in the growths, especially the main branches, avoid making the far-twine too tight. Many trees have been ruined because no room has been left for expansion. Plums may also be dealt with when time permits, and here fruit-buds will form on the main branches of the trees, so the current year's growth is cut back to two or three buds. It may be necessary to tie in a few new growths to fill up the space, especially with trees that have already covered their allotted station, and young examples should have their main growths left almost intact. This, however, will depend upon the vigour of the tree.

Fruits Under Glass.

Late Grapes.—Where the berries are ripe it will be necessary to keep a close watch on the bunches and decaying berries should be removed at once. Keep the atmosphere dry, and to prevent the house getting damp, pot plants should be placed in another structure. A little fire-heat will be needed, but the night temperature ought not to exceed 50°, with a rise of a few degrees during the day. Ventilation is desirable when the weather is favourable, but during wet periods care should be taken to keep out as much damp as possible.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.).

Castleford, Cheltenham, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Rhubarb.—Lift about half a dozen medium-sized stools and leave them exposed on the surface of the soil until wanted for forcing. As a result of this exposure to the rigours of winter they will respond more readily to a little forcing when applied.

Seakale.—Arrange a number of crowns (quantity according to requirements) in a box or flower-pot among sandy soil and place in the mushroom-house if at work; failing, which place under the staging in the stove or forcing-house, thoroughly excluding the light. This method will furnish an early supply.

Potatoes.—If pits were only partially covered when storming, they should now be finished off, but a little ventilation should be permanently provided. This is best done by inserting small, firm wisps of straw along the ridge of the pit, say, every 3 ft., and in the case of round clamps, one at the apex.

Celery.—If an early frost of some severity sets in, cover the plants with some wheat straw, or bracken if available. Lay on the protecting material loosely. When the frost yields, move the material down between the trenches with a wooden rake.

General Work.—Take advantage of frosty mornings for wheeling dung or soil on to the positions where it is required. Carry on with digging and trenching operations as expeditiously as possible, but never dig down frozen soil.

The Hardy Fruit Garden.

Planting.—If the ground has been prepared and the trees have come to hand, planting should be proceeded with without delay. Perhaps the most common mistake made in planting is that of planting too deeply. The aim should be to keep the roots as near the surface as possible, so that they may be under control. By pursuing this system the trees have the advantage of a comparatively warm, well aerated rooting medium; moreover, they can be fed as required from the surface, and the effects of continued drought can be countered by top-dressing and watering. Pits 12 ins. to 15 ins. deep are quite deep enough. The bottoms of the pits should be flat or slightly convex. They should be sufficiently wide to admit of the roots being stretched out at full length. Cut away any damaged or diseased roots and shorten any extra long bare roots. If some maiden loam can be mixed in with the excavated soil, it will prove beneficial. Stone fruits especially will be greatly benefited by a moderate admixture of old lime mortar. Tread the soil firm as it is

being filled in. Stake, tie and label each tree and finish off by applying a mulching of rather light manure.

Pruning. The pruning of Apple and Pear trees should be dealt with as circumstances will permit, choosing open, dry weather for the job. Summer pruning having been duly attended to, the operation will be confined to spurring back the shoots, to two buds as a rule. In the case of young, partially developed trees, any badly placed shoots should be entirely removed and leading shoots so selected and arranged as to build up a symmetrical specimen, whether grown in the open or trained against a wall or trellis (espalier). These leading shoots should always have the immature points cut away, as they can never serve as a good foundation for the future tree and, further, cutting these away encourages a break which is necessary for furnishing the ever-expanding specimen.

The Flower Garden.

Christmas Roses.—The true Christmas Rose (*Helleborus niger*) does not open its flowers till about Christmas, but *H. atropurpureus*, which is a much superior species, usually commences to bloom towards the end of October, and blooms more or less continuously throughout the winter. If these are grown in some quantity, a garden frame should be placed over the plants, not so much with any idea of forcing, but for the purpose of keeping the blooms clean. Abundance of air should be admitted to the plants night and day.

Bulb Planting.—This work should now be completed with as little delay as possible. Plants of doubtful hardiness, such as the early dwarf Gladioli, Ranunculi, Anemones, Camassias and Tigrids are best left until spring, or if planted now should be afforded some protection.

Sweet Violets.—If the culture has been correct, Sweet Violets should have been yielding a fair supply of autumn bloom. Keep all runners pinched as soon as they appear, and see that the plants do not suffer for want of water. Promptly remove all decayed foliage and do not coddle the plants.

Herbaceous Plants.—Specimens of doubtful hardiness should be protected either with rough coal ashes or dry, loose litter. Some coal ashes worked in among the crowns of Delphiniums will keep the slugs at bay.

Turfing.—This is a suitable time for carrying out any odd turfing operations, as it gives the grass a chance to root before winter sets in. Only turf of first-class quality should be used.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Celsia Areturus is a much smaller plant than *C. cretica*, but is very useful for furnishing the stages in the conservatory. If seed is sown at this time the resulting plants will flower early next summer, and another sowing made early next year will give flowers towards the end of summer. This plant is really perennial, but the best results are obtained by raising fresh stock from seed. *C. Areturus* only requires cool greenhouse treatment, and during the summer months may be grown in a cold frame.

Salvia patens.—This beautiful blue-flowered plant is generally grown for summer bedding, but at this time it is very charming for the cool greenhouse. This plant has tuberous roots like a Dahlia, and may be propagated in the same way, although the best results are obtained from seed. For flowering at this time the seed should be sown towards the end of March. Good plants may be grown in 6 in. or 7 in. pots and during the summer should be grown outdoors. There is a good white-flowered variety of this *Salvia*.

Veronica speciosa.—There are many beautiful varieties of this species, and all are very useful for furnishing the conservatory during autumn and early winter. If propagated at this time by means of cuttings, fine large plants will be secured for next year, while another batch should be propagated during the spring. If the plants are slightly pruned back after flowering, they may be potted on, when they should make fine large specimens. During the summer they should be grown outdoors, standing them on an ash-bed in an open, sunny position.

Calceolarias.—The large-flowered herbaceous varieties should be potted on as they require it, using a light rich compost. If it can be obtained, some old mushroom-bed manure is excellent for

young with the potted soil. The plants should be grown in a cool place at all stages of their cultivation. They should be lightly fumigated at intervals to prevent attacks by green fly. There are many beautiful and dainty varieties of *Calceolaria* and hybrids which should be increased and grown by plant lovers who like something out of the usual run of plants. There are some charming varieties which resulted from crossing *Calceolaria* with the large-flowered herbaceous *Episcia* and a batch of seedlings usually gives a wide range of colours and size of flower. Some of the varieties that are nearest the species *Calceolaria* in size and colour have retained the violet scent of this species. As many of the varieties have the dense woolly tomentum of *Calceolaria*, they require careful attention as regards watering during the winter months, and every care should be taken to keep the foliage dry, as it is very apt to damp off during the dull days. There are some fine selected varieties which are propagated by means of cuttings, and some of them are by no means easy to propagate successfully. The best plants are usually obtained by re-rooting the young soft tops from the first batch of cuttings. This, of course, applies to quite a number of other plants. *Calceolarias* of the shrubby section, such as *CC. Chirani*, *integrifolia*, *Allardii* and *Burlinghi*, that were propagated some time ago should be potted on as they require it. If stock is short, the young tops can be rooted, and will probably in the end make the best plants.

Begonias.—The winter-flowering varieties are now coming into bloom, and should be kept neatly staked and tied. When removed to the greenhouse they should have a position at the warmest end of the house. The variety *Mrs. Petersen*

is rather slow-growing, and it is an advantage if it is propagated at this time. Young soft shoots now root very readily. This plant can also be propagated by means of leaves like the other varieties of *B. Gloire de Lorraine*. This variety is excellent for indoor decoration, as its dark foliage and flowers are very effective under artificial light.

Tropæolum tricolorum and **T. Jarrattii** are two slender twining species that make pretty specimens for the cool conservatory. Dry tubers can usually be purchased during the autumn; four or five roots may be planted in a rosin pot. They only require a cool greenhouse, and should be sparingly watered until growth commences, when light sprays of Hazel about 3 ft. in length should be inserted in the pots for them to clamber over. *T. azureum* is a beautiful blue-flowered species, but so far as I know it has not been in cultivation for some years.

Scilla sibirica and **S. bifolia**, although quite hardy, are very charming when grown in small pots or pans for the small unheated greenhouse. They thrive in any good garden soil. When potted they may be stood in a cold frame, or even outdoors until such time as it is desired to place them indoors. *Scilla campanulata* (syn. *hispanica*), of which there are blue, white and rose-coloured varieties, is in all forms very beautiful for the unheated greenhouse, although one seldom sees it used for this purpose.

Chionodoxa Lucilæ (Glory of the Snow), of which there are several varieties, are very charming when grown in small pans for the same purpose, as also are some of the best *Muscari* or *Grape Hyacinths*.

Royal Botanic Gardens, Kew.

J. COULTS.

INSECTIVOROUS PLANTS—IV

Pinguiculas and Nepenthes.

UPON a casual examination of these two plants side by side—a Butterwort and the magnificent Pitcher Plant of the stove—one would almost certainly say that they stood at opposite ends of the scale, both in interest and complex structure. One a native of our own land growing freely as a hardy plant, the other a denizen of the tropical Bornean and other forest lands where brilliant birds and butterflies flit around amid vegetation no less gorgeous than themselves. Closer scrutiny, however, will reveal that there is not much to choose between them in their marvellous power to carry out their object, and that the humble *Pinguicula* is fully as efficient as the more striking *Nepenthes*.

Here is a plant of the common Bog Violet, Butter Root or Butterwort (*Pinguicula vulgaris*)—let us catch a small fly and “feed” one of those greasy-looking leaves. We drop the insect upon this leaf. It sticks upon the surface, and at once those glistening glands begin to pour forth their digestive fluid. As they do so the edges of the leaf roll slightly inwards so that the captive is directed more nearly towards the centre of the leaf and the process of digestion and absorption goes forward. Once more we have witnessed a remarkable example of flesh-feeding by an innocent-looking plant.

With the Butterwort, however, this is not all. If not omnivorous, it is certainly a very cosmopolitan consumer, to which a varied diet by no means comes amiss. Provided the nitrogen is there, the Butterwort has the power to “gobble” thus eaten seeds of other plants that may be blown upon the leaf surface by wind or other agency. Many people are under the impression that the name “Butterwort” is derived from the greasy or buttery appearance of the leaves, but this is not so. The name was acquired from the curious use to which the Lapps put the leaves in curdling the milk of the reindeer. Fresh leaves are gathered and laid upon a filter, and the warm milk poured upon them. Two or three days are

allowed to elapse while the milk becomes sour, and it is then separated from the whey and eaten. Once a supply of this milk has been obtained it is not necessary to use fresh leaves, for a small quantity of the already soured fluid poured into new milk carries with it the property necessary for curdling the new milk, a fact which is largely made use of in Sweden and Norway as well as Lapland.

The plant is quite an easy one to grow and well within the scope of any garden that can provide a boggy spot that is *never* allowed to dry out and where a peat bed can be put down for planting the roots. Plant firmly in a tully sunny spot and be sure that the soil never becomes dry and you will find that the Butterwort thrives splendidly. Seeds are the simplest mode of propagation, and to raise these the most convenient method is to sow them immediately they ripen in pots filled with sandy peat. Do not bury these seeds too deeply, and to ensure a sufficiency of moisture sink the pot to half its depth in water so as to keep the soil in a state of saturation.

There is quite a good number of species, the best of all being the Irish Butterwort, *Pinguicula grandiflora*. This makes a rosette of pale green fleshy oval leaves, and it flowers freely from May to July, the flower-stem varying from 3 ins. to 6 ins. in height and carrying violet blue spurred flowers. The common Butterwort (*P. vulgaris*) also produces a rosette of oblong fleshy leaves from 1 in. to 3 ins. long and several stems 6 ins. to 8 ins. high. These latter bear violet flowers with a long spur. In *P. lusitanica* the leaves are oblong in shape with a short stalk, the flowers—which are produced from June to October—are a variation on the usual violet blue in that they are lilac with yellow throats and a short incurved spur. The Scotch Butterwort (*P. alpina*), again, produces rosettes of oblong green leaves, which are slightly hairy on the upper surface. The flowering-time of this is early—May and June—and the blossoms very distinct, pure white and having a hairy yellow throat.

Turning now to the *Nepenthes*, to see which one must visit a house where the atmosphere is steamingly moist and very hot. One soon forgets all about the heat, however. The pitcher proves not to be a “flower” but an extension of the leaf blade. When the plants are young these leaves are quite unlike the adult and end in a hooked crest slightly hollowed in the lower portion. These hooks serve the same purpose as tendrils do for other plants, and in a state of nature these hooks cling round neighbouring plants and so gradually lift the plant higher and higher, until it is sufficiently raised into the light for the pitchers to be useful.

The pitchers are of two distinct forms, both being found at times on the same plant. The lower pitchers—as a rule—are globular, the upper are tubular, while—in a few species—a funnel form is seen.

Over the surface of the leaf are distributed numerous secreting glands, so that any sweet-loving insect which chances to alight there will probably be tempted to explore further. Now follow on down the tendril from which the pitcher depends. Here, again, small patches of sweet secretion are exuded. Lured on and on, the unsuspecting insect reaches the lid of the pitcher. Having fed so generously in such perfect security, all alarm is allayed, and it is only a step further upon that shining surface of destruction. Beneath the curved edge of that treacherous rim are more large sunken glands rich with promise, and in attempting to reach this it is a ten to one chance that foothold is lost and the insect precipitated into the death-pool that waits below.

When one looks at *Nepenthes bicalcarata*, one should notice those two strong, sharp spines that form the top of the high neck. One may be sure that they are not placed there just by chance. Where they grow, there is a small lemur which often attempts to rifle the pitchers of the dead insects they contain. Those two spines are so placed that they would just catch him by the nape of the neck and so throw him headlong into the pitcher too. “Wonderful” is but a weak word to describe such a marvel. Naturally, so unique a plant has evoked considerable interest among those interested in hybridising, and a very good number of hybrids now exist. The largest known species is *N. Rajah*. The species *N. Sanderiana* is a good example of the small globular type of pitcher, rather drawn in at the waist and with the cap drawn well down over the mouth. In colour these are a bright red-brown, splashed, marked and variegated all over with light green. Another very attractive form with short bulbous pitcher is *N. Dominii*. In this case the ground colour of the pitcher is bright light green, sparsely mottled with light red. *N. mixta* is a good example of the long tubular type of pitcher. The rim of this is much reflexed at the brim and ribbed in bright red crimson. The ground colour of the pitcher—dull yellow—makes it very conspicuous, especially as it is marked and blotched with crimson.

Culture is a matter of interest to but few, as a minimum winter temperature of 60° to 65° is necessary to keep them in good health. The plants are usually grown in teak baskets filled with fibrous peat, and the atmosphere needs to be kept almost at saturation point, so hungry are the plants for atmospheric moisture. Propagation is by means of cuttings, taken off in spring and inserted under a bell-glass in a warm propagating frame. The plants do not like direct sunlight, but at the same time they should always be grown near the glass and shaded only when necessary, so as to keep them as dwarf as possible.

H. W. CANNING-WRIGHT.

Don't give them a chance

Band your trees with Tactite. It catches and holds the moths—the enemies of apple trees. Only one application is necessary, it does not run, and remains "tacky" throughout the season.

If any difficulty in obtaining supplies please write to sole manufacturers, WILLIAM COOPER & NEPHEWS LTD., BERKHAMSTEAD.

ERROL Fruit Tree Specialists PERTHSHIRE

GARDENING AT WEMBLEY PARK

One of the most attractive features of the exhibition at Wembley should be the wide expanse of garden grounds which are to surround the buildings at the British Empire Exhibition. The arrangement of the landscape effects and the gardens is in the hands of Mr. Edward White, the well-known garden architect.

Before Wembley Park was pulled to pieces it was rich in natural beauty, and the architects changed the lay-out with the idea of preserving as far as possible the best of the old trees. There will, consequently, be a suggestion of maturity and an air of an exhibition. Many trees, of course, had either to be destroyed or transplanted, and last spring a large number of trees 40 ft. high, weighing up to six or seven tons, were moved under Mr. White's directions. A special tree-shifting machine was built for the purpose. The late spring encouraged the taking of risks not usually justifiable, and practically all the trees have survived, including even a big Chestnut that was blown over when in full leaf during the early summer. Nurseries to-day are very short of big trees, but about 700 forest trees up to 70 ft. in height have been secured. Many large evergreen trees and shrubs, especially Rhododendrons, have been prepared for transplanting, so that the grounds should be well furnished in spite of many difficulties.

The garden arrangements are in three sections: (1) The exhibition grounds generally; (2) the gardens of the Dominions and Colonies; (3) the gardens of horticultural exhibitors. The gardens in the first section cover about 30 acres, including the roadways and the new lake, which is a quarter of a mile in length. The old seven-acre lake at the north-west entrance has been filled in and the site turned into pleasure gardens enclosed by a fine colonnade. The main central avenue has altogether about 600 yds. run of flower beds and borders fronting the chief Exhibition buildings. The new lake, which runs east and west, is crossed by four bridges and contains several islands. The banks are treated in ornamental fashion, and should offer some good pictures. A big rock garden has been made in which seven or eight hundred tons of stones have been used. A cascade in the rockwork is crossed by a section of Old London Bridge, which has been presented to the Exhibition by the contractors. Landing stages have been made to serve a large number of pleasure boats, and the lake ought to be a very popular feature.

The supremacy of the "Geranium" is over, and for garden colour dependence is being placed on relays of herbaceous perennials specially prepared for planting. The opening display will be given by 100,000 British-grown Darwin Tulips. An idea of the quantities of herbaceous plants required is given by the fact that there are 5,000 Delphiniums in reserve.

The horticultural industry will be represented by exhibits covering 1½ acres in one of the most important parts of the grounds. It is, of course, a serious and expensive undertaking for a nursery firm to have an exhibit of this kind in an attractive condition for so long as six months. It is hoped, however, and there is little doubt, that those firms who have had the courage to make gardens will reap the full reward of their enterprise.

CATALOGUE RECEIVED.

Messrs. William Outbush and Son, Limited, Barnet Nurseries, Barnet, Herts.—Herbaceous, Alpine and Bulbous Plants.

Hedysarum multijugum. This is a loose-lobed, somewhat straggling, deciduous shrub which makes amends for a certain inelegance of form by possessing a pretty grey-green foliage of graceful fern-like, or pinnate, leaves, and abundant racemes of bright rosy-lilac, pea-shaped flowers which are produced from midsummer to October. *H. multijugum* is a good plant for growing in a light, warm soil with full exposure, and it may be used for covering low retaining walls or rocky banks with good effect. It attains a height of some 4 ft. or 5 ft., but it is usually seen with the branches peezed down, thus inducing a more bushy growth. It is a native of Mongolia and is hardy.

For the Waterside. *Saxifraga peltata* is quite distinct from most members of its extensive family, the majority of which are dwarf and admirably suited for the rock garden. The Umbrella Plant, as *S. peltata* is occasionally named, is well adapted for the bog or the edge of a stream, where it is seen at its best if given a rich rooting medium. It has large fleshy leaves, sometimes 1½ ins. to 2 ins. across, produced at the top of a stem some 2 ft. or 3 ft. in length. With the approach of autumn the leaves assume a coppery tinge, and as a foliage plant, *S. peltata* is a fine acquisition to the bog garden. It produces large heads of rosy-pink flowers in the spring and, after these are over, the foliage begins to develop. Where sufficient space is available it should be planted in bold groups, when it is most effective, and it may be associated with such things as *Rodgersia podophylla* and *R. pinnata*, both fine foliage plants. They appreciate a liberal root-run and if they are employed in small bogs by the rock garden will need fresh soil occasionally, otherwise they are apt to present a starved and stunted appearance.

The Pearl Berry. That delightful trailing plant, *Margyricarpus setosus*, known also under the names of Pearl Fruit and Pearl Berry, hails from the dry mountain sides of Chile, and is well adapted for the rock garden, where it should be planted so that the trailing growths can rest on a dark-coloured stone. In such a position its numerous white berries are very conspicuous, and if birds are not troublesome, it remains in full beauty well into the winter months. Plants suitable for clothing large stones are none too plentiful, that is if we do not desire too much repetition of the more common plants, such as *Arabis* and the like. In the Pearl Berry we have a pretty, uncommon plant that should be represented in every rock garden. It is evergreen and requires an open, sunny situation, where the soil is of a loamy nature. If this is on the heavy side, a portion of peat may be added with advantage. Propagation is effected by cuttings and division. Cuttings root readily during the summer months if placed in a frame or under a bell-glass. The plants can be divided during the autumn or spring months.

A Beautiful Rock Rose. Among the yellow *Helianthemums* of medium size *H. alyssoides* must rank with the choicest. The true plant makes a somewhat dense spreading bush up to 1½ ins. or more in height and twice as wide, the slender branches and narrowly oblong, pale green leaves being covered with a greyish down. The flowers are 1 in. to 1½ in. in width, the petals being a deep golden yellow without a blotch, a richer colour than is seen in any other Rock Rose of its class. These blossoms are borne on very hairy terminal corymbs, and while they are most numerous from the late spring to midsummer, the species is seldom out of flower until October. *H. alyssoides* is a native of the Spanish Peninsula, and it is quite hardy in any of our western and southern counties where its nearest allies, *H. tomentosum* and *H. f. unicolor*, prove reliable. Like most of its race, it enjoys full sun and a well-drained, gritty or rocky soil which should not be

too rich. It is easily propagated by cuttings taken in the late summer. The true *H. alyssoides* is still uncommon in gardens, though others frequently bear its name.

The Box-leaved Milkwort.—This is a charming little shrubby plant for almost any situation in the rock garden or woodland. It appears to prefer partial shade, though it will do quite well in full sun, and a cool root-run of sandy peat or gritty loam and leaf-mould containing a few buried stones is what it enjoys by way of soil. *Polygala Chamæboxus*, as it is botanically called, is an evergreen with dark green, leathery leaves about the size and shape of those of the common Box. The foliage, however, like the whole plant, varies a good deal, some forms having larger and rounder leaves than others. Considerable differences may also be noted in the height, some plants creeping in a close mat no more than 4 ins. high, while others will mound up into dense cushions 6 ins. deep. In the type species the pea-shaped flowers have ivory "wings" and a "keel" of pale yellow. But in the variety *purpurea* the blossoms are not only larger but the wing-petals are a rosy lilac, the "keel" being a rich citron yellow. This delightful shrublet is seldom out of flower in some gardens, and in most it can be relied upon to bloom in spring and again in autumn. It is perfectly hardy, being a native of the Alps of Switzerland and Austria.

Hardy Orchids.—We have received the prospectus of the new edition of M. Correvon's work, "L'Album des Orchidées d'Europe," which has been out of print since 1905. It is now being published with six new plates at the same price as the original edition in 1899, namely, 20fr. After the end of the year the price increases automatically to 25fr. There are in all sixty-six colour plates depicting the sixty-seven European species. Intending subscribers should write to M. Henry Correvon, Floraire, Chêne-Bourg, near Geneva (Switzerland).

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

GLADIOLI DISEASED (A. H. J.).—The Gladioli was attacked by a fungus known as *Botrytis*. In the particular plant sent the disease was confined to the top of the plant and the corns sound. If the others are like it, they can be saved if they are lifted this autumn and have the tops removed. Gladioli should not be planted in the same place again. In any case you will need to lift the corns each autumn.

FRUIT UNDER GLASS.

GRAPES UNSATISFACTORY (J. B., S.W.).—The Grapes are suffering from the difficulty that exists in regulating moisture and temperature. It is also likely that they are receiving more moisture than is actually necessary. It will, of course, be plain that the methods of ventilation, etc., adopted when fire-heat was available are not likely to be effective when the sun alone has to be relied upon.

THE GREENHOUSE.

LAGERSTREEMIA INDICA (A. M.).—This plant is a native of tropical and sub-tropical Asia. It requires warmer and moister conditions than the Oleander, hence can only be grown outside in this country in the most sheltered gardens of the south and west. We have seen bushes in the mild climate of Falmouth and Penzance as much as 6 ft. to 8 ft. high, the specimen at Falmouth being perhaps the best. The Crêpe Flower, to use its popular name, was formerly a very popular shrub for warm greenhouse culture. A large bush planted out in one of the borders of the Mexican House at Kew flowers freely every year, the leathery panicles of rose pink blossoms being very attractive.

LESS THAN HALF PRICE.****An Exceptional Opportunity.**

No garden, however small, is complete without a Sprayer, in fact a Sprayer is absolutely essential to obtain best results. During the War we supplied a considerable number of our well known Four Oaks Knapsack Sprayers—Rubber Diaphragm type—to the Government, and we have just re-purchased a small quantity back again, which have never been used. They are made of copper but painted Service grey colour. They have various special additions to the ordinary machines, and the price to-day would be £5 each. We guarantee them to be in perfect working order as new. We will send one machine carefully packed, carriage paid, on receipt of 50/-, but cash must accompany all orders. We would supply 2 machines for 90/-, carriage paid.

Please mention this Paper when ordering.

Do YOU know PARSONS'

WORCESTER BERRY?

If not, you have yet to learn of one of the most useful berries in cultivation;

and WHY?

It has **proved its worth** as a decided marvel in berry-bearing fruits, viz.:

As a Cropper.

As a Jam or Jelly Fruit, or for Tarts.

As a resister of Big Bud (or Mite) and Mildew.

Owing to heavy demands I have only a limited quantity, but offer, as far as my stock will permit, as follows:

Bushes or Single Cordons .. 2/6 to 3/- each
Extra Strong Fruiting Bushes .. 3/6 to 5/- each

Double and Treble Cordons or
Fan Trained, for Walls,
Trellis, etc., Extra Strong
Fruiting .. 3/6 to 5/- each

Packing and Postage extra, viz.:

1 plant, 9d.; 2 do., 1/-; 3 do., 1/3; 4 do., 1/6; 6 or more, carriage paid.

It has attracted enormous attention when exhibited at Shrewsbury, Harrogate, Glasgow and Edinburgh Shows, and the opinion of some hundreds who tasted it was "a delicious fruit."

If you have not seen above, ask for a copy of my New Fruit List **FREE**, with Coloured Plate of my Berry, Press Extracts, and Testimonials.

My List includes **ALL THE BEST** in APPLES, PEARS, PLUMS, etc., and my Worcester Grown **FIBROUS-ROOTED** Trees may be relied upon for **BEST RESULTS** and **QUICK RETURNS**.

EDWARD J. PARSONS, F.R.H.S., Fruit Specialist,
BARBOURNE NURSERIES, WORCESTER.

Notes from Maidstone.

GRAPE VINES & FIGS

The best Grapes are described in our list, which is sent free. We will not attempt descriptions in this limited space.

SHRUBS FOR THE ROCK GARDEN

THE list of shrubs which may be usefully employed in the really large rock garden is a practically endless one. Such tall-growing plants as the Common Broom and its varieties and the white-flowered *Cytisus albus* may often be used effectively where space is ample.

It is rather, then, to shrubs suitable for the rock garden of moderate dimensions that attention will be directed in the following notes. Such shrubs divide themselves at once into three classes. Class 1 will contain those kinds which are of an attractive habit of growth and (or) valuable for the colouring of their foliage but of which the flowers, if they bear any, have no special attraction; the majority of these are, in fact, conifers. In Class 2 will come all the tiny flowering shrubs which so much enhance the appearance of the rocky ledges, and in Class 3 must be placed shrublets valuable chiefly for their fruits or the colouring of their foliage in autumn.

There is a bewildering list of conifers suitable for the rock garden. Of the Norway Spruce, *Picea excelsa*, alone there are enough forms to stock a good-sized garden entirely; but, unfortunately, the nomenclature in nurseries is very confused and it is not easy to come by plants true to name. The better way is to purchase these plants after personal inspection; the name is, after all, of less importance than the habit of growth. A few good and desirable forms which one has a fair chance of procuring true are vars. *pygmaea*, *Clanbrasili-ana*, *nana*, *elegans* (usually listed as *Remonti*) and *Remonti*. The last named forms a very distinct egg-shaped bush, *pumila* is flat-growing, *nana* a congested "upright," *Clanbrasili-ana* pudding shaped, while *elegans* is conical. These dwarf Spruces seem

specially suitable for the rock garden. Another race which has almost equal claim consists of the very numerous dwarf forms of *Cupressus* (*Chamaecyparis*) *obtusa*. Very interesting and beautiful is *C. o. nana densa*, but many forms of *C. o. Tetragona* and *C. o. lycopodioides* (some of the latter Japanese) are equally attractive. There are, of course, dwarf Firs, Cedars, *Arbor-Vitæ*, Cypresses (true and false), *Cryptomerias*, Junipers, Pines, Douglas Firs, Yews and Hemlock Spruces, to say nothing of forms of the yew-like *Podocarpus* and *Cephalotaxus*, and the Umbrella Pine (*Sciadopitys*). Some of the dwarf Pines in particular are good, though it is doubtful if many of the special forms are better than *Pinus montana* var. *Mughus*, as it may readily be raised from seeds. For the rest, those who wish to go deeply into the question of miniature conifers should procure Mr. Murray Hornibrook's book, which has to a great extent brought order out of chaos in this direction.

Apart from conifers, shrubs for the rock garden which are cultivated mainly for the quaintness of their growth or the beauty of their foliage

belong very largely to the genus *Veronica*, which, largely herbaceous in the Northern Hemisphere, is entirely, or almost entirely, shrubby in the Southern. The very great majority of these shrubby Veronicas, indeed, came originally from New Zealand. Some of the quaintest for the purpose in mind are *cupressoides*, *salicornioides*, *epacridea*, *lycopodioides*, *canescens*, *Catarractæ* and *Hectori*. *Cupressoides* and *salicornioides* are much confused in nurseries, but, though some botanists consider *salicornioides* a form of *cupressoides* (*V. cupressoides variabilis*), the plants are, from the gardener's point of view, quite distinct. *V. cupressoides* makes upright cypress-like growths—it is generally many-headed—and is green, whereas the spreading sail-like growths of *V. salicornioides* are of a fairly bright yellow colour. The names fairly describe the club moss-like *lycopodioides* and the curious *epacridea*. *V. Hectori*, though quite distinct, is somewhat in the way of the last. *V. Catarractæ* approaches more closely in appearance to some of the trailing herbaceous kinds, and *V. canescens* is one of the most minute of trailers with foliage so small that

the whole plant might easily be overlooked.

Of more ordinary habit are the pleasantly grey *pinguifolia*, almost a small *V. Traversii*, but with foliage of a different grey; *glauco-cerulea* with very handsome steel-blue foliage; *loganioides*, heath-like with freely produced white flowers; and *Guthri-ana*, a tiny kind with very blue foliage. *V. glauco-cerulea* is botanically a form of *V. pimeleoides*, a plant after the style of *V. pinguifolia*, but rougher and scarcely worth a place.

One wee evergreen *Euonymus*, *E. radicans*, is delightful when rambling over a stone, and there is a good variegated form.

Another foliage shrub which is useful in the fair-sized rock

HEATHS, CONIFERS, AND OTHER DWARF SHRUBS IN THE ROCK GARDEN AT HALLINGBURY.

The great genus *Rhododendron* should, no doubt, have been touched on when we were considering ericaceous plants, but miniature *Rhododendrons* may be used in a rock garden, and used very effectively, whence all others of the Heath tribe are banished. A recent article on

(To be continued.)

THE SNAKE-ROOTS

THERE are about a dozen known species of *Cimicifuga*, variously called Bug-worts or Snake-roots, all natives of the north temperate regions of Europe, Asia and North America. They are spiræa-like, hardy border perennials, several of which closely resemble one another, but differ mainly in their season of flowering and the height each one attains. They belong to the *Ranunculus* family, and are closely allied to the genus *Actæa*, the coloured fruits of which are attractive in the autumn and useful for the purpose of house decoration.

Considering their handsome appearance, it is strange that they are so little grown in gardens, but this may be due to their being so often seen in poor condition in borders, where they are much injured by drought. They should be grown in deep loam in partial shade, such as that produced by a deciduous tree, preferably near water, and when well established will repay the planter with their splendid and plentiful foliage and inflorescences, composed of branching spikes of white or cream-coloured flowers. The taller-growing kinds, like *C. cordifolia* and *C. foetida*, may be used for the ornamentation of the margins of lakes and streams in conjunction with *Spiræas*, *Irises*, *Osmundas* and such-like plants. Here they would be seen to great advantage, with luxuriant foliage and handsome flowers.

Cimicifugas are easily propagated by division of the crowns in early spring, and by seeds, which are best sown as soon as they are ripe in well worked soil on the north side of a wall and allowed to develop as much as they will before transplanting. They dislike disturbance, and one only sees them at their best when they are left alone for several years and allowed to become well established. Some eight species are now in cultivation.

C. AMERICANA.—This is a neat-growing tufted plant, 2ft. to 3ft. high, with compound leaves of elegant habit. The flower-spikes are erect, in panicle form, with the primary spikes nearly 1ft. long and nearly 1in. in diameter, while the flowers are white. It flowers in July and August, and is a native of North America.

C. CORDIFOLIA is a much stronger plant, one of the finest kinds in the genus, with something of the habit of *Spiræa Aruncus*. The large leaves, of handsome appearance, vary in length and breadth from 6ins. to 10ins. The black-tinted stems are from 4ft. to 6ft. high, and they bear spikes of closely arranged flowers, the larger anthers and dull colouring of the filaments of which give a tint of cream to the whole spike. The inflorescence appears slender compared to the vigour of the plant, but the number of spikes produced and the stiffly erect habit compensate for this. It is only suitable for borders of some size or for waterside planting, where it is boldly effective. It flowers in September and, like the above, is a native of North America, where it is usually found growing in shady woods on the high mountains of Carolina.

C. DAURICA is an elegant plant from North-Eastern Asia with much-divided compound leaves and stems 4ft. to 5ft. high. The stems are slender, but very tough, and they bear branched spikes of pure white flowers, the primary spike nearly

species for the rock garden gave information which it would be futile to attempt to summarise here, but a word must be said for the rather tender, but O! so gorgeous, Kurume Azaleas, of which the slow-growing bushes smother themselves with blossoms in a great variety of colouring.

erect and about 1ft. long, the secondary ones more lax, and as they interlace freely they have been compared to the well known *Statice Suworowi*, but that is, of course, less drooping in habit. *C. daurica* is an easily grown plant, and will thrive in a shady border in rich soil. It produces its flowers in August.

C. ELATA is a tall-growing species some 6ft. to 8ft. high, with more distinctly lobed and thinner biternate leaves than *C. cordifolia*. The flowers

late in October; especially is this the case if the plant has been checked by drought in summer. A denizen of the woodland, it is more partial to shade than any of the others, and is more readily injured by hot sun. As its name implies, it is a native of Japan.

C. RACEMOSA, "Black Snake-root."—This, one of the most ornamental species, was introduced into this country from North America in 1732. When thoroughly happy in its surroundings it will attain a height of 6ft., and with its dozen or more tall flower-stems, terminated by slender racemes of pure white flowers, it presents a highly effective picture. The curiously twisted habit of the flower racemes has earned for it the name of *C. Serpentaria*. *C. racemosa* has a handsome mass of broad and much-divided leaves, and succeeds best in rich, moist woodland, where in the more open spots it establishes itself and increases freely by means of self-sown seeds. It is an admirable wild garden plant, and is also

CIMICIFUGA JAPONICA (ON THE LEFT) AND *C. SIMPLEX*.

of this are not showy, and are borne on much-branched inflorescences. It is a native of the shady woods of Oregon in North America.

C. FOETIDA.—A native of Europe and Northern Asia, this species bears a general resemblance to the above, although it is quite distinct. It is not so tall, and the white flowers in large branched panicles are more showy. A distinct feature of this plant is its unpleasant smell and the large carpels that succeed the flowers. It is a good woodland plant, and self-sown seedlings come up freely in moist, loamy soil, thus in a short time producing an effective group.

C. JAPONICA (syn. *Pityroserpa acerinum*).—Recently there seems to have been some confusion between this species and *C. simplex*, which is, however, quite a distinct plant. *C. japonica* grows about 2ft. high, with entire basal leaves and ternate stem leaves with broad leaflets. The white flowers are borne on erect stems in smaller spikes than in *C. simplex*, and it is generally a much inferior plant. Another distinction is the absence of or very short pedicels of the flowers and fruits. It is one of the oldest known species grown in our gardens, and has been in cultivation for a long time. Often, it does not bloom till

useful in the border, as it flowers during the months of July, August and September.

C. SIMPLEX.—Although one of the most elegant autumn-flowering plants, it is only of recent years that this species has attracted much attention. It has been in cultivation for a long time under various names, as *C. japonica* and *Pityroserpa acerinum*. These two latter names are synonyms, and *C. simplex* differs from them in its more robust habit and more decompound leaves, as well as in the mature fruit carpels, which in *C. simplex* are stalked, while in *C. japonica* the carpels are practically sessile on the stem and usually fewer in number. *C. simplex* is a native of Japan, and makes a neat bush about 3ft. high, with good-sized triternate leaves and slightly nodding inflorescences 6ins. or more in length. The flowers are pure white and produced during September and October, lasting for a long time in full beauty. It is one of the easiest to grow, and does not mind lifting and division, although established plants produce a greater quantity of longer racemes. Like all the others, it prefers a shady position in moist soil, but will succeed in the open if supplied with plenty of water when in full growth.

W. L.

NOTES ON SOME LATE-FLOWERING PLANTS

ONE of the most charming of autumn-flowering plants belongs to a race that is peculiarly lacking in species of quality, viz., the family of Knot-woods. *Polygonum vacinifolium*, however, is a treasure that would be valuable enough to uphold the reputation of a genus more ill-favoured than that of which it is a member. Elegant in habit, beautiful in leaf and branch, and possessing a temper of indestructible sweetness, this little creeping shrublet would be delightful were it never to bear a flower. When autumn brings a ruddier flush to its mat of foliage and the extremity of every slender twig is tilted in a spire of rose pink blossom, then, indeed, *P. vacinifolium* becomes one of the loveliest objects of the garden year.

Though willing to prosper under almost any conditions, this plant is never quite so happy as it is with its roots in a cool vegetable mould and its trailing branches mounding over some old stump or mossy rock with full exposure to the sun. Though it does not object to hanging head downwards as a wall plant, or flopping over a ledge, its tendency is to go upwards, and its flower-spikes are never so numerous and gay as when they are crowning the summit of some hummocky object which it has enmeshed.

We grow the above about open spots in the woodland, and associated with it is *Borago laxiflora*, another delightful plant of which the azure bells may be found swinging at the arched tips of the slender, semi-prostrate stems from spring to winter. Few would credit such a gentle thing

there are still of the *Asclepiadea* set. The best of their blues, however, has not the delicate quality of the colour of this *Borago*, of which the peculiar refinement is not exceeded even by the wonderful sprays of *Omphalodes cappadocica*, young plants (seedlings) of which can always be relied upon to give a hearty response to the autumn rains in this garden.

Yet another plant of irreproachable taste, of which the flowers will adorn any cool, half-shady place in woodland or rock garden at this season of the year is the Winter-flowering Periwinkle (*Vinca difformis*). The blossoms of this beautiful species are about the size of those of *V. major*, but the segments of the corolla are sharply pointed and they are of a cold, icy whiteness, suffused with just a hint of palest blue. Though a native of Southern Europe, *V. difformis* appears to be hardy, but it should have, and none more fully deserves it, a sheltered corner, lest its flowers be injured by frost. Whether *V. acutiflora* is merely a geographical form of the above or the same thing, the botanists must decide. It is, at any rate, equally lovely. Indeed, the only difference which a mere Gentile has been able to discover between the twain is that while the white of the one is most delicately shaded with blue, that of the other is invested with the faintest wash of lilac.

An 8 in. bunch of vivid watercress green that came here as *Cineraria lobata*, and which never lost heart during the driest weeks of summer, is now a blaze of quaint little yellow stars. This might be a glorified Groundsel or a pauperised

flowers smell of new-mown hay, and even though it has borne these all summer, its earlier efforts were as nothing compared with the constellation which it now raises aloft on slim branching stems, blazing defiance at the lowering sun.

Though we have had some frost and anything but a kindly autumn, the honoured house of *Erodium* is still well represented. These little Stork-bills are such tireless sun worshippers, and so optimistic withal, that they will lie in a dog's sleep for a week, their half-opened flowers waiting for the rain and gloom to pass, when the butterfly flowers will expand their jaunty wings to the grateful light. Nor do they feel like giving up until the year grows late, and even then many a flower will perish unopened like young forsaken swallows in an autumn nest.

Thus only a week ago there were clusters of blossoms, closed, yet showing their delicate pink, on *E. supraannum*, perhaps one of the daintiest of the race. But there were others, as there are to-day, more greatly daring, and among them *E. maritimum* must always rank high as a southerner of admirable courage under depressing conditions. Also bearing several heads of flower is *E. autumnum*, which for many of these mid-autumn weeks has been a most delightful object, for not only is its silvery foliage most tasteful and delicate in design, but its flowers are large and of a most exquisite pearly whiteness. Much might also be said of sweet little *E. chamaedryoides*, first and last to bloom, and the highest compliment which I can give this bantling is that she will never be displaced by her china pink sister *rosea*, even though the latter must be numbered among the gems which are beyond price.

Linaria alpina always reappears in October, a rare and dainty combination of blue-grey, violet and orange. Then there is that irrepressible midget, *L. equitridoba*, which is still swarming about some shady steps which it has claimed as its own and, not content with that, it has darned a bristly green mop of *Armeria*, big as a two-pound loaf, with its yarn of green and studded it all over with tiny purple flowers.

Asters do not, here, proclaim the sovereignty of purple over all other colours as they are wont to do in many autumn gardens. If they did those wee *Linarias* might have stood a feeblish chance of claiming recognition. An old clump of the very splendid *A. Amellus* King George, however, and another of *A. Rudolph* Goethe, have been proving the wonderful endurance of their big, violet-purple flowers in all sorts of weather for unnumbered weeks. Compared with these ornate fellows *A. Thompsoni* nana might be considered a shrinking apology, but it is just that modesty in habit and colour and form which makes it so appealing. This is a shy bloomer here, and its pale blue lilac flowers with the curiously small eye, usually come late and continue throughout the autumn. Another downy-leaved species which carries on to the last is the 3 ft. *A. pyrenaicus*, with shaggy heads of blossom in a cool blue-purple and a predilection for wet feet.

Lower or dry places that it is, *Achillea tomentosa* can always be relied upon to put up a good show of its golden flowers with the autumn rains, and the variety King Edward with larger heads and flowers in sulphur yellow is also a good late bloomer. *Sedum spectabile* will keep its rosy pads of blossom for some time yet, as will *SS. Ewersii* and *Sieboldii*, and that strange little member of this family, *S. amplicaulis*, which, having thrown off its mask of withered leaves in autumn, has covered its trailing stems with tufts of foliage in a fresh sea green.

N. WALES.

THE AUTUMN-FLOWERING *POLYGONUM VACINIFOLIUM*.

as this wit sufficient courage and resource to enable it to hold its own with its companions, many of them native, of the woodland flora. But it does, and does it with such a nice regard for the feelings of its neighbours that it never seems to place a seedling in the wrong spot. *B. laxiflora* is even more generous with its flowers at this season than it is earlier, and blue is a very precious colour in the garden to-day. Gentians

Ragwort far gone in moult, for the rays of those yellow stars only number five, and they are set so far apart and at such odd angles that they give the flower a dishevelled look. But this weird creature deserves a passing tribute because it kept throughout that droughty period not only its life but its smiles, while others perished. Its spoon-shaped, scalloped leaves are, moreover, more than ordinarily pretty, the queer little

CHINESE RHODODENDRONS

Some Interesting and Distinct Kinds

WITH the present wide and very real interest in the cultivation of hardy shrubs we often nowadays see borders set apart for rare and uncommon plants. One such border might very well be set apart for distinct and interesting Rhododendrons in any garden where these plants are favoured. Such a selection should appeal, too, to readers with small gardens, for, while there are points about them which are attractive and absorbingly interesting, none of those brought under review is likely, at least for numbers of years, to grow into a big bush.

Most of the plants possess some particular trait or characteristic which will appeal to and engross the attention of the enthusiast. These distinct features may be in habit, foliage or flower, the season of blossoming, or in cultural requirements. The selection of positions for planting is important. The majority, if not all, of those mentioned should have shelter from the midday sun, while those which flower early must, if success is to be obtained, have protection from the east. This points to a west border or sloping bank as the most suitable position for the larger number.

Special stations may be selected and prepared for individual plants, but, at least during the first years of planting, a cultivated border is preferable. Plants of small stature invariably thrive better in association with well tilled ground than as isolated plants with cultivated rings. The upkeep as to hoeing, weeding and mulching is also less exacting.

R. SOULIEI was one of Mr. E. H. Wilson's earlier (1903) introductions. He describes it as a common bush 3 ft. to 8 ft. high near Tachien-lu, Western China, at 9,000 ft. to 10,000 ft. The leaves are heart-shaped and of a distinct dark metallic green, and the ends of the twigs in May terminate in clusters of three to six blossoms. The wax-like flowers are open, saucer-shaped, a dainty pale rose shade in some, while other plants have white flowers. Though cultivated plants mature seeds fairly freely and these bloom in four or five years from sowing, Rhododendron Souliei is puzzling in its cultural requirements. The two best plants at Kew are on a west bank nestling close against the bottom branches of a shrubby *Arbutus*.

R. ORBICULARE is another of Mr. Wilson's introductions. He first found it in the woodlands of Tachien-lu, Western Szechuen, at about 10,000 ft. in 1904, and again in 1908. It is very distinct in habit, forming quite formal rounded bushes much wider than high. Native specimens are described as rounded evergreen shrubs up to 10 ft. high, but I have not seen plants more than one-third this height in cultivation. This Rhododendron has also been named *R. rotundifolium*, it and the name *R. orbiculare* referring to the roundish or orbicular leaves. The rich rosy red flowers are borne in loose trusses six to eight, rarely more, in number, campanulate and 2 ins. to 2½ ins. across. The flowering season is April or early May. This is quite one of the most charming of the Chinese species, but not among the easiest to cultivate. This fact will, no doubt, cause the enthusiast to give the plants special attention, as seedlings are being raised very successfully. Growing in woodlands and thickets suggests that shelter will be one essential. A hybrid raised at Kew, *R. orbiculare* pollinated with *R. Williamsianum*, is fairly intermediate between the two parents with rose-coloured, bell-shaped flowers.

R. STRIMFOLIUM in colour may be very well described as a Chinese *R. Thomsoni* or *R. fulgens*, such a glowing crimson are the flowers on the plants raised from seeds collected by Mr. George Forrest in Yunnan. There are also said to be forms with rose coloured blossoms. In a wild state the plants vary from 2 ft. to 8 ft. in height.

The oblong leaves are dark green above, glaucous white beneath. The crimson flowers are bell-shaped, up to about twelve blooms in a truss. As Mr. Forrest found *R. normifolium* at 9,000 ft. to 12,000 ft. elevation, it should be quite hardy, yet as the flowering season is usually April, shelter is necessary.

R. BRACHYANTHEMUM is a native of Yunnan. Mr. Forrest collected seeds on the Tai Range at 10,000 ft. to 11,000 ft. altitude, where he describes it as an evergreen shrub from 2 ft. to 3 ft. high. The features of this plant are the dainty pale

THE INTERESTING RHODODENDRON OLEIFOLIUM.

RHODODENDRON RACEMOSUM IS BY SOME CONSIDERED ONLY A WIDELY DIVERGENT FORM OF *R. OLEIFOLIUM*, ILLUSTRATED ABOVE.

flowers, three to five, sometimes more, pericarpis bell-shaped, 1mm. or rather less across. A curious feature is the saucer-like pale green calyx, five-lobed, 2mm. to 3mm. wide. A valuable character is that the flowering season is June. Our two plants of this species were received as *R. repens*, which is also a native of Yunnan. The true *R. sulphureum*, however, has rather larger leaves, richer yellow flowers 1mm. or more wide, a much smaller calyx, and the flowering season April. *R. sulphureum* is a shady and moisture-loving species, judging by Mr. Forrest's notes: "Collected on moist, shady ledges of cliffs on the Lah Range at 9,000ft. to 10,000ft. and in shady ravines on humus-coated rocks up to 14,000ft."

R. himalaicum is a dwarf compact-growing species introduced by Mr. Forrest from Yunnan. It has dark leathery green leaves, up to about 3ins. long and half as wide, covered beneath with a brown felt. The rich deep red flowers are funnel-shaped, five to seven or more blooms in a truss opening during May. Found by Mr. Forrest in woods at 12,000ft., it should be quite hardy, but will, no doubt, thrive best where the plants get some shade. Giving this species a liberal mulching of leaf-mould will induce the stems to root, thus providing a ready means of increase by layering.

R. oleifolium.—This species is very much confused with *R. racemosum*; in fact, there are numerous intermediate forms that suggest the two may be the extreme forms of one plant. The confusion is really due to both producing the flowers from the leaf-axils of the previous year's wood. All the plants we have grown of *R. oleifolium* are smaller in stature than is *R. racemosum*, but with larger leaves. In *R. racemosum* the flowers are freely produced, four to ten, or twelve in a cluster, but in *R. oleifolium* they are borne singly or in pairs, rarely three or more, pale rose or white in colour. Both species are readily increased by cuttings and layering. Mr. Forrest introduced the true plant from Yunnan in 1909.

R. oreotrephes.—In foliage and flower this introduction of Mr. Forrest's is usually singled out for admiration by ladies because of its attractive glaucous foliage and pale lavender or lavender rose flowers, the shade of colouring and spotting of the flowers varying considerably. The flowering season is April and May. It is a plant which requires shelter and liberal mulching. Wild plants are said to attain from 15ft. to 20ft. in height, but with us, at least, it is slow in growth. *R. oreotrephes* is another outcome of Mr. Forrest's Yunnan expedition of 1909, which gave us so many new and interesting plants.

R. ruficolum, with rich plum purple blossoms, immediately attracts attention when well grown, but it is with some a wayward plant and apparently not easy to accommodate. Found by Mr. Forrest in Yunnan during 1910 at 14,000ft., the plants appear to be perfectly hardy. Spreading in habit, it resembles somewhat in appearance the European species *R. ferrugineum* and *R. hirsutum* and, like the last named, is said to grow on a limestone formation. Perhaps, therefore, the ideal spot for this gem is in the rock garden.

R. Wilmsii is a delightful low-growing plant spreading over the ground, with us, always seeking the shade and moisture of rocky boulders. This liking is very pronounced. The front of the group of some twenty plants is open and sunny, and we invariably lose one or two in the front each year, replacing them with rooted layers from the shade, but they only bloom. Given shade and moisture the plants spread, nesting closely to the surface of the stones and producing

freely the small ovate dark green leaves. For so small a plant it has quite large flowers, these being bell-shaped, rich pale rose in colour, 2ins. to 2½ins. across. There are two to four, rarely more, flowers in a loose truss. Mr. Wilson introduced this species from Western Szechuen in 1908. In addition to easy propagation by layering, cuttings are fairly easy to root.

R. molle was first introduced by Mr. Wilson in 1909 from Western China. It is a bushy evergreen shrub requiring shelter and some shade, as the flowering season is March and April. In a wild state some of the plants are epiphytes, growing in the forks of trees. There are two forms, one with rose and the other with white spotted flowers. Our best plants are growing among the roots of an upturned

tree butt in front of an evergreen tree and facing west.

R. spinuliferum is one of the most distinct and remarkable of all *Rhododendrons*. Discovered in Yunnan by the Abbé Delavay about 1907, it is the least hardy of all the species mentioned in these notes, growing outside only in sheltered positions. Even so, it has not, so far, had to face a really severe winter. The plants are freely clothed with bristles and hairs, and the leaves are lanceolate up to 2ins. or 2½ins. long. The flowers are tubular, about 1in. long, red in colour, borne several together in clusters at the ends of the shoots. Though not perhaps an ideal comparison, I always think of *Correa cardinalis* when looking at this plant in flower.

Kear.

A. O.

A CHARMING WHITE-BERRIED SHRUB

(HYMENANTHERA CRASSIFOLIA)

In the few places where this interesting shrub is grown it stands out very conspicuously among other berried shrubs during the autumn and winter months by its compact habit, neat foliage, but more particularly by its white berries, which are borne in great profusion. It forms a close compact bush from 4ft. to 5ft. high and twice as much through, of a semi-evergreen habit, with stiff, cylindrical or somewhat angular branches, which are covered with ash-coloured wrinkled bark thinly beset with whitish strigose hairs. The almost stalkless flowers, which are borne in the leaf-axils, with five brownish reflexed petals (which are longer than the sepals) cannot claim to possess any interest from a decorative point of view, being very inconspicuous; but when the bush is laden with its masses of white berries it is really valuable, for there is but a limited number of white-berried shrubs. The fruits, too, remain on the plant long into the winter. The thick leathery leaves are alternate, about 2in. to 3in. long, scarcely ½in. broad, obovate, entire, rounded or slightly notched at the apex, tapering at the base into a very short stalk.

A native of New Zealand, the species was introduced into this country somewhere about 1875. Its habit, neat foliage and white berries give it a distinctive character, while botanically it is an interesting shrub in that it belongs to the *Viola* family. *Hymenanchera* is the only hardy genus of that family which is of a shrubby nature.

In Hooker's "Flora of New Zealand" the

berries are described as blue-purple, but probably this description was made from dried specimens, when the white skin had become transparent and allowed the purplish pulp which surrounds the seed to shine through. A similar effect may be noticed on the outside of some of the growing berries where they are exposed to full sun. The plant is readily raised from seeds, and thrives in any ordinary soil in an open position. It is rather remarkable that so interesting and beautiful a shrub should not be more cultivated.

Botanic Garden, Cambridge. F. G. PRESTON.

HYMENANTHERA CRASSIFOLIA IN FRUIT.

GARDEN DESIGN—II

NEARLY all new grounds, even though quite small in extent, are composed of separate gardens, each having its own particular character, and it is in this subdivision and the proper contrast and relation of the different parts that much of the art of garden-making consists. Terraces, lawns, rose gardens, herbaceous borders, and rock and wild gardens must all be correctly proportioned to the total area of the site.

As well as being of suitable size, gardens should be well placed, that is to say, each particular garden should have the proper aspect and be in the best place for that particular garden. Rose gardens should be sheltered from the north and east and yet have a fairly open aspect. Neither the rose garden nor the tennis courts should be too far from the house.

Much has been written about the respective merits of formal and informal (or "landscape") gardens. Generally, gardens will be less formal in treatment as they are farther from the house, although it will often surprise and please to come unexpectedly upon some small formal garden set amid the more natural parts of the grounds. Gardens of shrubs and lawns, and so-called wild gardens, may, if properly planned, be some of the most beautiful and attractive of all.

Let us start again from the house and consider planting and the nature of it for the different gardens. Not too far away one should have colour, colour for the greater part of the year and a lot of it, and here let me say that if one's gardens are set in woods or trees so that one has backgrounds of green, one cannot well have too much colour, but if the surroundings are walls, one needs to be careful. At the risk of repetition I must repeat that the terraces and gardens near the house should be formal, but formality will be changed to richness if the planting is properly arranged.

The terraces and gardens near the house should be resplendent with colour for most of the year. There should be a foundation of permanent planting, such as *Ceanothus* in its different species and varieties, *Bignonia*s, *Irish Junipers* (most serviceable for the way in which they can be used to accentuate formal design), as well as *Roses* and other climbers on any low walls, on house walls, pillars and pergolas, and down the sides of steps.

Near the house there must be finished planting with nothing untidy about it. Flowers differ in quality with the difference there is between silk and velvet on the one hand and, say, cotton fabrics on the other, and near the house one must feel no jarring note between the tastefully decorated interior, and gardens that may often here be something in the nature of outdoor rooms.

For the permanent planting use such plants as *Delphiniums* (blue *Delphiniums* may often be used where blue *Lupins* would seem too coarse), *Liliums*, perhaps *Tree Lupins*, the various *Artemisia*s (Southernwoods), *Lavender*, *Mimulus*, some perennial *Asters*, *Campanulas*, *Scabious*, *Pentstemons* and numbers of other plants.

The plants which constitute the permanent planting should be skilfully grouped to form a setting for the bedding plants and biennials that will be used for their continuity and freedom of flowering, and for the added touch of richness they will impart. In the autumn one may plant great masses of *Darwin Tulips* midway or rather back in the border, so that lower plants in front may partly hide their stems and act as a foil to their lovely colours. As well as *Tulips*, one could have *Narcissi*, but this family is really more suitable for the more natural parts of the gardens.

Numbers of *Hyacinths* can be planted in front to grow close to the paving or turf, always in masses of one sort by itself, and *Wallflowers*, but some

SHOWS PLANTING SUITABLE FOR A PAVED GARDEN.

of these are of cruder colouring and must be carefully placed. *Violas* can be treated as permanent residents and left undisturbed until they become weak and straggly and need replacing, and they will flower so early as to be in bloom with the *Tulips*, that is, if they are planted soon enough. Double white *Arabis*, *Myosotis* and *Aubrietia*s in their colours that seem to tone with everything will also be planted for early spring effects.

The fresh delicate greens of the permanent masses of *Delphiniums* and other plants will, all the time that they are growing, be the best possible background for the bulbs and other early flowers, and after these have finished there are a host of things to choose from for the summer. *Tree Fuchsias* are always useful, they need little care during the winter—to keep them secure from frost is enough—and they should be grown into as large plants as possible. *Bezonias* (both tuberous and fibrous rooted), *Heliotropes*, *Carnations*, *Marguerites*, *Zonal* and *Ivy-leaved Pelargoniums* ("Geraniums"), almost all of the often despised bedding plants can be used here with the best results. Only remember always that they are to be grouped and never arranged as formal bedding, and grouped with due regard to the scheme of planting as a whole. November may seem an unsuitable time to talk of summer bedding, but it is easy now to visualise results for future seasons.

To turn to more permanent planting—the planning of which is as interesting as it is hoped the results will later on be beautiful—so far as herbaceous plants are concerned it is well first to decide the height and habit of growth that is required to

obtain the effect desired, and carefully to consider the colour scheme as a whole before actually selecting the plants to be used.

For reds one should be careful in the choice of plants: some are good natured enough to tone with anything, the ruby red *Pentstemon Southgate*

Gem being one of these, but many reds are inclined to be crude unless carefully placed. Blues are always welcome, and go with nearly every other colour except perhaps some reds and browns. Browns and golds and yellows and bronzes may be grouped to make harmonies of their own. *Heleniums*, *Gaillardias*, *Torch Lilies* and the bronzy foliage of some of the Chinese *Paeonies* can be most effective. To arrange interesting and beautiful groups in the borders is an art in itself. Having decided the colour scheme as a whole, one may proceed to carry this out with a succession of groups each lovely in itself, and yet all subservient to, and helping towards, the general effect.

Grey foliage plants, of which there are quite a number, are always useful. Nearly every colour looks better against grey. *Lavender*, *Santolina* (although its yellow flowers are sometimes troublesome), *Carnations*, *Stachys lanata*, *Alyssum* and *Artemisia*s of sorts are some of the plants with desirable grey foliage.

It is important to have as much green as possible for the backgrounds. In nature one sees nearly all colour as a relief against green in some or other of its many shades. The vision of a park with reds or scarlets as the predominant colouring is too hot to think about, yet it is not unusual to see something like this in small gardens, where bricks or buildings supply the red background with other colours piled on thickly.

In herbaceous borders it is better to err on the side of having the groups of one sort of plant too big rather than too small. *Delphiniums*, *Asters*, *Lupins*, *Hollyhocks*, *Anchusa italica*, to be most effective, should be in groups as large

A HERBACEOUS BORDER.

The form of plants is as important as their colouring.

as the size of the borders will allow. It goes without saying that most of these tall-growing plants will be at the back of the borders. Some of the larger plants should, however, be brought well to the front or the border will be too regular in outline. Also it must be remembered that form is even more important than colour or, at all events, that form comes first and colour should be built on to it. It is the use in the best possible way of the wealth of materials, the interweaving of the threads of form and colour, that,

colour is to be obtained not only from flowers, but that numbers of trees, shrubs and plants are invaluable for the colouring of their foliage alone.

Trees, shrubs and flowers, turf and water, the dignity of straight lines and the beauty of pleasing contours are materials enough, like the notes of music, with which to make innumerable harmonies in endless ways. Not the least of the pleasures of garden-making is the limitless scope of its possibilities.

PERCY S. CANE.

ABOUT SEEMLY FLOWER POTS AND BULB BOWLS

BY a fortunate development of taste the variety of plants grown in pots for decoration of the house or conservatory is nowadays increasing. Geraniums, Primulas, Scillas and other flowers are delightful and showy indeed (though they require a good deal of labour), and so, too, are the shrubs commonly seen in pots, such as Azalea indica, Daphne, Forsythia, Hydrangea, Cypripedium, and, latterly, Viburnum Carleii. But outside the conventional repertory there is a vast store of suitable plants which might well be drawn upon more freely for decorative purposes. In a later article I will hazard some suggestions as to plants worth adding to the repertory, but for the moment let us deal only with the initial problem of finding suitable pots.

The ordinary red earthenware flower-pot is inoffensive enough in a conservatory, and in an entrance hall or wherever plants can be massed together in some quantity the pots can generally be masked more or less effectively. The Ferns so commonly used for this purpose are often unsuitable; plants of bolder, shapelier form, such as Funkias, may be preferable. (Readers of Miss Jelk's "Colour in the Flower Garden" will remember her pictures of the use of Funkias for masking the pots of speciosum Lilies and Hydrangeas.)

But no matter how skilful one may be in the masking of pots, there will remain occasions when one has to allow the pot, or its container, to show itself. The plant has to be isolated on a terrace or in the house, and it is then that the

to the artist, makes the construction of gardens so interesting an occupation.

Nearly everyone has his or her favourite colours and flowers, but some colours can be more generally used than others. Blues can be used almost anywhere, and in a blue border or garden, if one's space allows room for it, can be included as many as possible of its shades. If one does have a blue garden, one should see that it is set in green surroundings and, with the exception of, it may be, a little white, it should be kept to blues. Blue flowers with green turf and, perhaps, grey stone-walling are always beautiful together.

As in Eastern embroidery, one may, in parts of the principal borders, work up to a riot of the richest colours. Deep blue and purple Delphiniums, orange Lilies, crimson Pentstemons and Hollyhocks (crimsons are generally safe, but beware of scarlet!), apricot and yellow Day Lilies, with always plenty of green foliage, and the bronzy leafage of purple-leaved Plums and Paeonies will make a brave show. One must not forget that

problem of finding a container for the garden pot becomes acute. What is one to do with a little bush of, say, Cydonia Sargentii, or of Corylopsis, or Rhododendron praecox or R. Princess Alice, or of orange Azalea, when it comes into the house in its rough garden pot. The pot may have a good wholesome natural colour, but it will usually look much too rough and raw to fit in as part of the decoration of a modern room. And the trouble is that nobody seems to bother their head about producing a decent pot-container. Why is this? Lots of people are interested nowadays in the potter's craft: quite a number of good potters are at work. Yet, so far as I know, hardly anyone has given an artist's thought to this much-needed commodity—a plain, lightly pot-container. The Poole Pottery has made some excellent holders for rather small pots; I do not know if they have tried making them for the larger sizes. The pottery that was started by Mrs. G. F. Watts at Compton produced, I believe, some good earthenware pots for terraces. And I expect there are potters here and there even now who are producing just what I am looking for and looking for just such customers as myself. But the fact remains that whether through ignorance or ill-luck or simply because the thing I am looking for is not being made, I do not know where to go to find the pot-holder I want.

The sort of holder I have in mind is moulded very simply on much the same lines as the common garden pot, with a well marked rim and a solid, rather conspicuous base. There should be no ornament, or only a very little: no garlands or built-up horns in relief. The colour should, I imagine, be rather quiet, not bright yellow nor pink nor blue like the dreadful glazed bowls with waved edges in which an Aspidistra darkens so many a window. There is a vivid green, however, which is delightful for such a purpose, the colour of malachite or of true emerald, a blue-green, not a yellow-green. It is the colour of the pottery which is, or was, commonly obtainable in the South of France, *i.e.*, at Carcassonne and, I think, in Spain. The glaze must be some simple one, within the reach of potters humbly equipped, but I never see the colour in modern English pots.

There are various beautiful whites which would be very suitable, such as the dull white used by the Upchurch Pottery in some of their finest work. And there is a black, not the matt Wedgwood black, but a more lively colour, such as Mr. Reginald Wells used in his Coldrum pots. Besides these colours there are all the beautiful neutral tones, and the dull, not too olive greens, that are within the potter's range. I have no knowledge of potting. I am only describing the ideal pot-holder I have in mind.

Besides the difficulty of finding the pot-holder, there is a lack of good bowls for bulbs. The bowls commonly advertised at the end of bulb catalogues are almost without exception bad in colour and form, and lacking in character. Metal bowls, such as the beautiful Italian utensils of copper and the plain copper preserving pans used for jam-boiling are among the best that I have tried. Why does not some enterprising firm or guild, such as the Artificers' Guild or the Design and Industries Association, set craftsmen to work on making bowls to meet this recently developed demand. Some of the Korean bronzes have just the required dignity of shape, and so, too, have the beautiful shallow Chinese bowls in celadon. Surely I am right in thinking that there are many gardeners, and many a householder, too, who is starved of gardening opportunities, who would gladly pay a decent price, not just a commercial "one-and-eleven-three" for a pot-holder or a bowl really well designed by contemporary English craftsmen.

A PAINTER.

CORRESPONDENCE

GARDENING IN ESSEX.

I THINK perhaps the enclosed pictures of my garden may be of interest to some of your readers. We are on the hills between Maldon and Colchester with a most beautiful view across the Blackwater River. Twenty years ago the garden was a very stony field with a few Gorse bushes about; all the ground round here, if left, very shortly reverts to heathland. It is a very

RHODODENDRONS AND STABLE MANURE.

I DO not think that "Formakin" will find many of those who have given most attention to the finer species of Rhododendron to agree with his recommendation of stable manure as a stimulant to growth (page 546). I have not seen his plants, and there may be peculiar qualities in the soil at Formakin requiring different treatment

and I claim that the result proved it to be beneficial. Cow manure is cool, and although I am enough of a sceptic to think that in the fine greensand of Leonardslee, Sir Edmund's plants would have flourished as freely without that supplement to their natural diet, it is certain that they suffered no injury from it. But the stable manure recommended by "Formakin" is hot stuff, and I cannot but think that its application might be the reverse of beneficial. "Formakin" takes as an example the hybrid Pink Pearl; I am more concerned about the natural Asiatic species. Rhododendrons belong to the Heath family, and it is well known to those Scottish farmers who have to deal with rough pasture that there is no more effective way of ridding such land of Heather than by feeding cattle grazing thereon with cake. Their droppings stimulate the growth of grass and the Heather gets choked out. But even such plants as Pink Pearl thrive luxuriantly without other treatment than an annual or biennial heavy mulch of leaf-mould, or, as I prefer, freshly fallen leaves that, decaying *in situ*, dissolve into leaf-mould. "The largest flowers of Pink Pearl I have ever seen," says Mr. Millais, "were grown in a made bed of sand and beech leaf-mould."

I must not be understood to underrate "Formakin's" experience, still less to doubt the accuracy of his description thereof; but having witnessed and followed the simpler treatment of Rhododendrons practised in most of the finest collections in Great Britain and Ireland, I am slow to be convinced of any advantage in the application of any animal manure. So long as *R. sino-grande* produces leaves 20ins. long and *R. calophytum* 10ins. long (measured this morning) my plants must be content with a dressing of leaf-mould. As for peat, the Asiatic Rhododendrons, except the lowly species that take the place of Heather at very high altitudes, never taste it till they are brought to this country, nor have the splendid plants grown in Cornwall any experience of it; nevertheless, in planting out we always put in some sand and pulverised peat as a good starting medium. Peat dug out of a moss and applied straightway is positively injurious, being heavily charged with humic acid; but six months' exposure to sun and wind makes it wholesome and digestible.

In his experiment of planting an unhappy *R. Nobleanum* in lime rubbish to test whether cow manure will enable it to survive, "Formakin" seems to disregard the latest research upon the biology of the genus Rhododendron, whence it appears probable that, while the Rhododendron itself has no antipathy to lime, the symbiotic fungus which clothes the roots and penetrates them with its mycorrhiza cannot survive contact with lime; and whereas the Rhododendron depends for existence on the nitrogen drawn from the soil by the fungus, the death of the fungus entails the death of its host. When Mr. Wilson and other collectors first reported that several species of Rhododendron had been discovered growing upon limestone, and even in talus full of limestone rubbish, British botanists were puzzled by a statement so much at variance with their experience of the genus; but Mr. Forrest has carried research further, establishing the interesting fact that in the Asiatic Rhododendrons growing in a limy soil the characteristic fungus grows on their leaves instead of their roots, presumably to draw a supply of free nitrogen from the atmosphere instead of fixed nitrogen from the soil.—HERBERT MAXWELL, *Monreith*.

MANURE as a mulch for Rhododendrons is very beneficial, though cow manure is to be preferred to that from the stable. Possibly the old idea that peat is a real necessity for successful

A READER'S PAVED GARDEN.

A LILY POOL IN THE SAME GARDEN.

difficult garden to run, as the soil is so hot and hungry. The lily pool shewn is very shallow—only about 18ins. deep—with large basins scooped out for the Water Lilies, which are planted in loam and turves, in which they do exceedingly well.—(Mrs.) E. M. TAYLOR.

from that of other places. "No doubt," says Mr. Millais in his great work on the genus Rhododendron, "the different exigencies of soil and situation sometimes require the employment of different treatments," and at Leonardslee the late Sir Edmund Loder used to apply decayed cow manure

Rhododendron growing in the few adherents in the wintered days. I am free from lime but the soil is quite satisfactory in which to grow this beautiful race of plants, but they will "get away" more quickly and better if peat and leaf-mould are placed about the roots when planting. Thus and an annual mulch of fresh leaves and manure will ensure success so far as soil is concerned. Moisture at the roots is a more important factor. The Rhododendron produces a mass of fibrous roots which do not extend far beyond the branches, and plants will readily respond to generous waterings in hot, dry weather. There will be many dissentients from "Formakin's" statement that R. Pink Pearl is an over-rated plant. If placed in full sun it is not satisfactory, for the colour soon fades, but in semi-shade, such as on the north side of a belt of trees, it is good, and possibly some experts would still place it among the best twelve. In full shade Pink Pearl is not satisfactory—it flowers less freely and becomes straggling.

A more difficult question than manure or soil is whether to plant in shade, semi-shade or in the open, and the question is answered by the requirements of each particular species or hybrid. One learns of these requirements only from experience. Semi-shade, such as woodland which has been cleared except for such trees as are reserved specially to provide shade, is the ideal position for Rhododendron growing, but some of us have not these ideal sites, such as one sees at Leonardslee, South Lodge, Sheffield Park or Exbury. Yet we would endeavour to grow and enjoy these beautiful flowers, and one is optimistic when he sees a huge plant of R. arboreum album said to be ninety years of age, with stems about 2ft. in circumference at the base, 20ft. to 25ft. in height and as far through, planted in full sun and fully exposed to the south-west. This specimen is growing in clay, and receives no help except that which it can obtain from its own decayed leaves. Varieties which stand exposure very well are R. arboreum hybrids, Fortunei hybrids (including Duke of York, Duchess of York and Mrs. Thistleton Dyer), R. emmabarinum, R. c. Roylei, R. Gauntlettii, R. Loder's White, R. Alice and the small-flowered R. yunnanense. The flowers of R. chartophyllum are not unlike those of R. yunnanense, but smaller, the plant is more bushy and of pendulous habit. It is a charming plant when in flower, and would look well in a border of mixed shrubs. We have it doing well and fully exposed to the south-west. The beauty of R. c. Roylei is seen at its best from the side the sun is shining. The flowers are then transparent and of a brilliant blood red colour. The beautiful new race of Dutch hybrids distributed by Messrs. van Nes and Koster are proving themselves quite hardy and to stand exposure very well. Some hybrids of R. discolor produce plants and flowers somewhat similar to those from Holland, and these late-flowering hybrids will prove of great value. There are some genies which will always insist on the coziest nooks, such as RR. Loderi, Falconeri, eximium, argenteum, A. Lindleyi, calophyllum and sutchenense, and to these may be added practically all the large-leaved varieties.—R. J. E., *South Hants*.

LING CHANGING COLOUR?

THE note in THE GARDEN of October 6 by H. Lindley about Heather changing colour is of more than passing interest, and induces me to record a somewhat similar happening I experienced some years ago while in charge of a large garden in Rutlandshire. The Heather was planted in clumps at the back and side of a rockery, and during the spring and on into summer the weather

set in very dry. The following season most of these Heathers flowered weakly and the greater part of them were of white or almost white colouring. This I attributed to the dry conditions of soil, the plants being somewhat starved by the lack of moisture for a long period and a loss of iron elements in the soil through those conditions. After flowering, a top-dressing was given, this being made up of a quantity of sifted spent chrysanthemum pot compost containing oyster shell, crushed mortar rubble and charcoal, to every barrow-load of which a barrow of well rotted oak and beech leaf-soil was added. The following season every one of the pink and rose coloured varieties resumed their former hues, while the tufts of Heather grew amazingly, which undoubtedly proved the lack of colour to be due to impoverished conditions. GEO. LOVLOCK.

A ROSE GROWING IN A STONE WALL.

I AM not sure that the enclosed photograph is suitable for reproduction, but I send it, as it may interest some readers to see a Rose growing in the joint of a stone wall. I noticed a seedling Briar growing, and when it was strong enough I inserted a bud of Zéphirine Drouhin in 1922 and the photograph shows the year old plant with three open blossoms and one bud. The plant is strong and healthy and bids fair to do well in its unusual quarters. It is surely a rarity from a joint in masonry to strong clay soil. The joint in which it is growing is about 2ft. from the ground.—H. C. W., *Longfeld*.

THE FIFTY BEST ALPINES.

I ENCLOSE a list of fifty alpine plants that I grow in my little garden at Dawlish. I have omitted non-flowering shrubs, not being sure how many of them are considered alpine. The plants I name are those which have succeeded best here.

Androsace lanuginosa, A. l. Leichtlinii, Alyssum spinosum, Aquilegia glandulosa, Aster Farreri, Arenaria montana, Alyssum saxatile citrinum, Bellis coerulescens, Campanula pusilla (Miss Willmott and alba), C. carpatia and its varieties, Ceratostigma plumbaginoides, Convolvulus mauritanicus, C. Cneorum, Crassula sarcocaulis, Daphne Cneorum, D. Verlotii, Dianthus alpinus, Dryas octopetala, Erodium chamaedryoides, E. chrysanthum, Erica carnea hybrida, E. cinerea atrosanguinea, E. vagans levernensis, Gentiana verna, G. Farreri, Geranium argenteum, G. lanceolatum, Geum montanum, Helichrysum bellidifolium, Lithospermum prostratum, Linaria alpina, Mentha Requienii, Micromeria corsica, Myosotis rupicola, Morisia hypogaea, Omphalodes Luciliae, Oxalis emicaphylla, O. magellanica, Phlox divaricata Laphamii, Potentilla fruticosa, P. nitida, Pentstemon heterophyllus, Ranunculus australis, Rosmarinus prostrata, Spiraea digitata nana, Verbena

chamaedryoides, Viola bosniaca, V. biflora, Wahlenbergia serpyllifolia, Zauschneria californica.—VIOLET C. BENTINCK.

CERTAINLY no two lovers of alpine plants will ever quite agree as to the fifty "best" plants for the rock garden. Climate, soil and general construction of the rock garden vary so much that a plant which is invaluable in one garden proves worthless in another. I imagine that your correspondent invites criticism on his selection of the fifty plants best suited to the average type of rock garden (including a small moraine), where plants which require very special cultural attention are not desired. If that is the case I would suggest striking out from his list the following as being too unreliable unless in the hands of an expert, viz.,

ROSE ZEPHIRINE DROUHIN GROWING IN A WALL.

Aquilegia alpina, Azalea procumbens, Cyananthus lobatus, Cypridium Calceolus, Daphne rupestris, D. Blagayana and Omphalodes Luciliae. Are not Soldanella Ganderi and Viola Bertoloni rather unproved as yet? Ononis cenisia also is too rare. I think the following list of fifty plants consists only of tolerably easy kinds, all of sufficient beauty to be worth a place on every rock garden: Aethionema Warley Hybrid, Androsace sarmentosa Chumbyi, A. lanuginosa, Aquilegia glandulosa, Arenaria balearica, A. montana, Asperula suberosa, Campanula Albionii, C. carpatia White Star, C. garganica, C. pulloides, Cytisus kewensis, Daphne Cneorum, Dianthus alpinus, D. neglectus, Dryas octopetala, Gentiana acaulis, G. Farreri, G. sinuata, G. verna, Geranium argenteum, Geum Borisi, Hypericum Kotschyannum, H. reptans, Iris gracilipes, Lithospermum prostratum, Linaria alpina, Onosma echinoides, Oxalis emicaphylla, Pentstemon Davidsonii, Phlox Douglasii, P. subulata Nelsonii, Potentilla nitida, Primula frondosa, P. pubescens alba (nivalis of gardens), P. Winteri,

Ramondia pyrenaica, *Ranunculus amplexicaulis*, *Saxifraga aizoon rosea*, *S. Burseriana* Gloria, *S. Elizabethæ*, *S. lantoseana*, *S. oppositifolia*, *S. Grisebachii*, *Silene alpestris* fl. pl., *Sedum spatulifolium purpureum*, *Sempervivum arachnoideum*, *Veronica saxatilis*, *Viola gracilis* and *Wahlenbergia serpyllifolia* major. I have purposely omitted all bulbs—one might indeed easily select fifty really desirable bulbous plants for the rock garden alone. —N. G. HADDEN, *West Porlock, Somerset*.

WITH reference to "Purley's" invitation to criticise his list of alpine, I think it would be hard to do so, as the list is rather a good one, but I will submit a list which I think includes some of the best, especially for their flowering qualities.

Achillea rupestris, *Æthionema ibericum*, *Androsace Chumbyi*, *Antirrhinum Asarina*, *Aquilegia corruca*, *Asperula suberosa*, *Aubrietia Dr. Mules*,

A. rosea splendens, *Campanula Abundance*, *C. pusilla alba*, *C. Portenschlagiana* (muralis), *Cheiranthus linifolius*, *Cistus lustranius*, *Convolvulus Cneorum*, *Coronilla iberica*, *Corydalis lutea*, *Cyananthus lobatus*, *Cypripedium spectabile*, *Dianthus casius albus*, *D. fragrans* fl. pl., *Draba brunifolia*, *Erythraea Massoni*, *Gentia sagittalis*, *Gentiana verna*, *Geranium sanguineum lanceolatum*, *Gypsophila cerastoides*, *Houstoniaerulea*, *Hypericum Henryi*, *Linum arborescens*, *Lithospermum prostratum* Heavenly Blue, *Lychnis Lagasce*, *Morisia hypogaea*, *Omphalodes verna*, *Onosma taurica*, *Papaver alpinum*, *Pentstemon Menziesii* Scandier, *Phlox nivalis*, *P. Vivid*, *Primula capitata*, *P. Cockburniana*, *Saxifraga apiculata*, *S. Burseriana* Gloria, *S. Irvingii*, *S. oppositifolia* major, *Thymus Serpyllum coccineus*, *Veronica pectinata rosea*, *V. Teucrium Trebane*, *Viola bosniaca*, *V. gracilis*, *Wahlenbergia saxicola*.—R. C. JOLLIFFE, *Oxford*.

The Flower Garden.

Planting Roses.—November is the ideal month for planting Roses, the leaves having duly performed their functions and yet enabling the plants to take hold of the soil before the dead of winter. It is taken for granted that the ground has been judiciously manured and deeply dug. If the roots of the plants have become dried up in course of transit, they should be steeped in water for twenty-four hours prior to being planted. Cut away any damaged or diseased roots and considerably shorten any long, bare ones. Excavate the pit sufficiently wide to admit of the roots being spread out full length. The bottom of the pit should be quite flat or slightly convex and of such a depth that the point where the bud was inserted should be immediately below the surface of the soil. Tread the soil firmly about the roots, and when the operation is completed, run the Dutch hoe between the plants. Label the beds, clumps or single plants according to the style of planting.

Sweet Peas.—Plants in small pots intended for early planting out should now be pinched to induce a short stocky growth; keep the plants near the glass. It is rather early yet to prepare trenches for the main planting, but the ground should be selected and the trench or trenches marked off. If natural stakes are available, the sooner they are secured the better.

Digging, whether single or double, should be carried through as soon as the work can receive attention. This, of course, applies to the mixed garden and where there are borders or considerable breadths vacant. It will be well provisionally to mark how the various spaces are to be furnished next season, and this in turn will determine to what depth the soil should be cultivated. Strong-growing gross feeders, such as Dahlias, require much more liberal cultivation than Antirrhinums and the general run of annuals.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

CONSERVATORY AND GREENHOUSE.

Shrubs for Forcing.—There is quite a large number of hardy shrubs and small trees that are suitable for growing in pots or tubs for furnishing the conservatory during late winter and spring. Many of them force readily, but where accommodation is not available for forcing, they may still be used, for if brought on in an ordinary greenhouse temperature most of them will produce their flowers several weeks in advance of the plants growing outdoors. The plants best adapted for this purpose are those that naturally flower early. Many of them, such as *Rhododendrons* and *Azaleas*, if lifted from the open ground at this time and placed in pots or tubs may be successfully forced. Others, such as *Lilacs*, give the best results when they are pot grown, and plants specially grown for forcing can usually be purchased from plant dealers. A pot-grown *Lilac* that has suffered no disturbance at the root will last in good condition for several weeks in a cool house, while plants lifted from the open may only last in good condition for a week. The same remarks apply to *Pyruses*, *Prunuses*, *Magnolias* and *Wistarias*. In using *Rhododendrons* for forcing, preference should be given to varieties that naturally flower early. *R. Rosa Mundi* is very free and may be had in flower at Christmas, while *R. Prince Camille de Rohan* is a good type of *Rhododendron* for this purpose. In fact, all the varieties that have caucasicum "blood" in them are suitable. Other *Rhododendrons* that respond well to forcing are *RR. precox*, *macronulatum* and *emasculum*. *Forsythia intermedia* var. *spectabilis* is the best of all the *Forsythias*. This plant forces well and may be had in flower at Christmas, and if placed in a cool conservatory remains in good condition for several weeks. It is invaluable for furnishing a supply of cut flower for house decoration. *Keria japonica* var. fl. pl. is very useful for early work. Among *Spiræas*, *SS. Thunbergii*, *arguta*, *prunifolia* fl. pl. and *Van Houttei* are all very beautiful and useful. *Pyruses* are also lovely, and are always much admired. The most useful are *P. floribunda* vars. *atro-sanguinea* and *purpurea*, *P. spectabilis* and the hybrid *P. Scheideckeri*. The genus *Prunus*, again, provides many fine plants for this purpose, including as it does the many beautiful species and varieties of Japanese Cherries; *P. persica*, which includes the beautiful double Peaches; *P. triloba* fl. pl.; *P. japonica* fl. pl. in pink and white varieties; also *P. pissardi*, the coloured foliage of which is very bright and attractive. *Acer Negundo* albo variegata is also very useful for its foliage effect, while the many beautiful varieties of the Japanese Maple, *Acer palmatum*,

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Broad Beans.—In this district we make a practice of sowing several lines of Broad Beans of the Longpod type during the early part of this month, and they are invariably a great success. They produce their crop a few weeks in advance of the spring sown, and they are rarely infested with the black fly. Select a well drained and sheltered spot and plant in double lines 2 ft. or 3 ft. apart—the seeds in the lines being from bins. to bins. apart and the lines about bins. asunder. Plant the seeds 2 ins. deep. If possible, the position should be sheltered from cold, cutting east winds, which do more harm than frosts and rain, especially when the plants are a few inches high.

Crops in Frames will need close attention during the next two or three months, damp being the greatest enemy. Every opportunity should be taken to remove the lights, thereby keeping the atmosphere fairly dry and the plants as hard as possible. Stir the soil between Cauliflowers, Lettuce, etc., at intervals, and afford a sprinkling of soot or lime if slugs are prevalent.

Peas.—Where a suitable position exists, such as a light well drained border with a south aspect, it is worth planting a few lines of Peas. The round-seeded varieties are best, and I have found The Pilot most reliable for sowing during November and December. It attains a height of 3 ft. or 4 ft., so the rows should be about that distance apart. Sow the seeds rather more thickly than is usual, and a close watch should be kept for slugs when the seedlings appear through the soil.

Globe Artichokes.—If we experience a spell of frosty weather, it will be necessary to afford the crowns some protection. Straw, leaves, or fern bracken will be found suitable, but the centre of the plants ought not to be covered for any length of time or they will decay.

The Flower Garden.

Bulbs.—Although earlier planting of bulbs has been advocated in this column, there is still time to deal with some kinds, especially May-flowering Tulips. All beds should now be cleared of their summer occupants, because it is not advisable further to delay such work.

Herbaceous Borders.—The lifting and replanting of herbaceous plants should be taken in hand, and, where new borders are contemplated, it will be necessary to proceed with the work at once. Borders that have been in existence for several years and have not been disturbed will need a thorough overhauling. Lift the plants, label them, and cover them with mats while the border is manured and trenched. The best method to divide herbaceous plants is to pull them to pieces with two forks and not chop them up with a spade. Use the outer or young portions for replanting. Borders that have received recent attention will only require a general clean up, a dressing of manure, and a light fork over. The Michaelmas Daisies, *Heleniums* and such like may be divided, but *Delphiniums*, *Pæonies*, etc., are best left alone. The colour scheme or arrangement of the plants must be left to the individual, and the width of the border should also be taken into consideration. A stiff formal appearance should

be avoided, and a few bold irregular groups generally will suffice to provide the necessary relief.

Lawns will require sweeping occasionally with a new birch broom, afterwards rolling the grass with a light roller. Any bare patches may be made good with fresh clean turf.

The Hardy Fruit Garden.

The Fruit-Room.—Constant attention is necessary to prevent the loss of fruits, more especially this year when they are so scarce. One bad fruit will quickly contaminate others, hence the reason for its early removal. No frost should be allowed to enter the structure, but excessive warmth and dryness are equally detrimental. Arrange the fruits in single layers so that they may be readily examined.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Jerusalem Artichokes.—If the stems have not been cut over, this should be attended to, and, as a wintery snap may occur at any time now, it will be advisable to protect a part of the crop with some dry littery material so that the supply can be maintained independent of the weather.

Ridging.—Those who have to battle with heavy clayey soil should, when trenching, throw the soil up in ridges like a fully earthed-up potato drill; this exposes the maximum of surface to frost and other weathering influences and makes the work of breaking up the soil at cropping-time much easier.

Pea Stakes.—Gardeners who have access to natural pea stakes (the best of all) should secure them as soon as convenient while the sap is down. If there is a choice, Beech, Elm and Hazel should have preference, both on account of tractability and lasting qualities; failing those kinds one must make the best of what is available.

Parsley.—If a sowing was not made in a frame to produce a winter supply, a frame should now be placed over part of the crop. Give abundant ventilation in open weather, but protect from frost by matting the frame. This is only intended for a stand-by during hard weather, so pick from the open whenever it is available there.

Fruits Under Glass.

The Orchard House.—All the pot trees will still be out of doors, where they should remain for the present. If they have not been plunged, they should be now, or the pots should be surrounded with some loose litter. These precautions are necessary to prevent injury to the roots by frost and also as a precaution against the pots being broken through the action of frost. Meanwhile the orchard house should be thoroughly cleaned preparatory to the trees being brought inside. Ventilate the house day and night.

Strawberries.—Should very wet or snowy weather occur, the pots should be accommodated in a cold frame, which should be freely ventilated. The plants should be kept on the dry side, but should not be allowed to become dust dry. If frame room is not available, the pots may be stacked on their sides, protection being afforded by means of mats if frost occurs.

are in vogue for growing in pots, as is *Acer japonicum* var. *acuminatum*. Other plants that are commonly used are *Staphylea trifolia*, *Deutzia gracilis*, *Viburnum Opulus* sterile and *V. macrocephalum*, also the sweet-scented *V. Carlesii* and *Xanthoxylum* *scorbiifolia*. *Wistarias*, of course, are extremely useful, and are best when pot grown. They should be brought in slowly in an intermediate temperature, for it given too much heat they usually drop their buds. *Laburnum* and hardy *Broom*s (*Cytisus*) may be used for the same purpose. From the number of plants mentioned it will be seen that there is a wealth of material to select from, and these plants should be more generally used for furnishing the conservatory during the earlier months of the year, when they give a spring-like effect indoors which is very welcome during inclement weather. All plants used for this purpose should be potted at this season, standing them outdoors until such time as they are required. The pots should be

plunged in ashes or surrounded with hay to protect them from frost.

Erica gracilis and its variety *nivalis* are very useful for furnishing the greenhouse at this time. They are grown in large quantities by several nurseries for the London market. *Erica melanthoides* is also largely grown for sale during Christmas. These plants are very popular and last in flower for quite a long time, and it is a great pity that they are not more generally grown in private establishments.

Freessias and *Lachenalias* that were potted early have now made considerable growth, and should be kept well up to the glass and be given plenty of air on all favourable occasions. The young growth of *Freessias* should never be allowed to fall over, else the plants never do well. Therefore, some timely support should be afforded them. Slender sprays of Birch or Hazel are very suitable for this purpose.

Royal Botanic Gardens, Kew.

J. COULTS.

NERINES

History—Cultivation—Appreciation.

I WOULD, personally, have preferred, had I followed my own inclination, to have headed this article *Guernsey Lilies*. Firstly, because I think the name *Guernsey Lily* is old enough to have the preference given to it, and, secondly, even if this be not so, it is the one that has been attached to one of the most striking plants that have ever reached European shores. The great advertisement of the "Mania," its long continued popularity and its hardiness in western gardens have combined to give such a commanding fame to the *Tulip* that the stir in gardening circles (or to use a much more ancient phrase, among the Curious), is, I expect, almost unknown. Unlike that great flower it has never become common. For one thing it is not hardy, or, to be more accurate in my generalisation, it was not, until the coming of Bowdoin, which, even in my Midland garden, lives through ordinary winters at the foot of a south wall. Secondly, it always seems to have been a shy bloomer. If one may read between the lines of tradition the first bulbs that ever came to *Guernsey*, about 1050, had this failing, as their descendants certainly have. Hence, we frequently come across the advice in old gardening books of last century to throw the bulbs away after they had flowered. There is but little doubt that the *Guernsey Lily* has been an awkward customer to deal with in English gardens ever since the famous Cromwellian General Lambert flowered it in his garden in 1659. It bothered such a keen and knowledgeable gardener as John Evelyn not a little, as anyone may see if they follow his remarks about "the *Narcissus* of Japan (or *Guernsey Lily*)" in his "Kalendarium Hortense" for April from the earliest edition in 1664 to that of 1701. These "curious" ancients thought very highly of it. Father Rapin, a French Jesuit, in his poem about gardens published in 1695, gives us a good idea of the estimation in which it was held both in France and in our own country and so we can reduce the anxiety of Evelyn to get it to succeed. I have chosen the translation made by Mr. Gardiner, the young sub-dean of Lincoln, who died at an early age.

"This delicate, yet skillful Florist often plant,
Let not vexation this fair beauty want;
And thou dost answer not your common care,
No cost nor labour on her dress or spare,
For should she but her conquering charms display,
From every fair she bears the prize away."

The beauty of what I believe to be the original "one and only" *Nerine sarniensis*—has of late years been augmented by the raising of an immense number of very beautiful hybrids of varied shapes and colours, so that we have not only the deep rose

of the old variety, but innumerable shades of red, many shades of pink and a broad-petalled white. There is good news to be told too about the way they flower. The "crab" of the race has been all along their shyness in blooming. In the first volume of the *Memoirs of the Caledonian Horticultural Society* (page 285, of the second edition), it is stated that in the island itself about the year 1800 only from fifteen to eighteen bulbs out of a hundred could be counted upon to bloom. I can readily believe it from my own experience. With some of the newer varieties it is quite different. Until the lengthening out of the war made things very difficult, I kept careful records of how almost every potted flowered, and I could point to many in which there were three or four bulbs of which the record was one to two bloom-units every year, the high-water mark being reached when three bulbs gave six flower stems. This freedom was undoubtedly helped by correct cultivation, but a very great proportion of my success was due to the innate propensity of the new-comers to respond to treatment which they appreciated. One cannot make a silk purse out of a sow's ear; one cannot make *sarniensis* into even a triennial bloomer. With a little knowledge of their wants many of the moderns, if there are three or more in a pot, give a yearly display of their charms. October, in England, knows no more fascinating or glorious sight than a collection of *Nerines* in the early morning or late afternoon when the sun's rays strike those wonderful umbels at right angles and transform the vegetable substance of the flowers into scintillating tinsel which more than rivals the brilliancy of the beautiful red Japen enamel. Believe me, the family is worth a house to itself. Its members are good tenants. They give so little trouble, and when the time comes that they must swarm, a good cold frame from which frost can be excluded will hold the overplus. One cannot kill a *Nerine*, though one cannot make it flower. It fills me with amazement to see what treatment they will put up with. If only one can keep them growing, with healthy foliage, from the time they appear, in October, until, in April, their yellowing sheaves the task of manufacturing food has been completed, little more is necessary except to give the bulbs a thorough good basking from May to August. They like a good virgin loam to which is added enough silver sand to keep it porous, and thorough drainage. All the feeding is done by liquid stimulants during the winter months, when the leaves are green. It is a mistake to overpot. They are a class of plants that like to feel their roots against the sides and bottoms of the pots; hence, repotting is only necessary once in three or four years. If the bulbs become so crowded that they burst their pots, no harm is done

except to the pots. It is their forcible way of telling one that they need dividing, or more room if they are to remain in one mass; in this latter case the ball can be bodily transplanted to a pot of a slightly larger size.

Seedling raising is tedious. I find it at least five or more, often six or seven, years before a new bulb will throw up its first bloom. Against tediousness may be set easiness. If the seeds, which, by the way, are green and never look as if they were ripe, are sown very thinly, say $\frac{1}{2}$ in. apart from one another, they may be left in their original seed pans until they flower. Not only is this an easy way of dealing with seedlings, but it economises room, as, if pantful of each bulb and its little offsets are put into $\frac{3}{4}$ in. pots, they take up a good deal more room than before they were moved. I will conclude as I began, by a few words on the name *Guernsey Lily*. It was originally known as *Narcissus japonicus rubido flore* or *Narcisse du Japon*, that is to say, *Japan Lily*. As far as I can gather from the books at my disposal, John Evelyn was the first person to call it the *Guernsey Lily*, or as he wrote the name the "*Guernsey Lily*." This was in 1664, in the first edition of his "Kalendarium Hortense," which was published as a sort of addendum to his *magnum opus* "*Sylva*," which may literally be called one of the foundation stones of England's Greatness. No "*Sylva*," no Nelson. It is as great as that. The name *Guernsey Lily* did not altogether catch on. At one time it was the *Japan Lily* and at another the *Guernsey Lily*. For example, John Laurence, Rector of Bishops-Wearmouth, in his "New System of Agriculture and Gardening" in 1726, gives both (page 424). He places it under the head of *Narcissus* or *Daffodil* and introduces it by saying, "It would be the highest injustice to the Crown and Glory, and King of them all to say nothing, or but little of the *Narcissus* of Japan." He then gives his version of how the plant got the name *Guernsey Lily*. It arose from the wreck of a ship from Japan on the coast of the island which contained some of these bulbs, which either lay neglected on the shore or which were given to some of the inhabitants. At all events their beauty very much surprised the good people when they first bloomed, and as the conventional tale ends, "they have lived there happily ever after," and for many years must have been a considerable source of income to the people of the little island. I like the ancient parson's enthusiasm. A bed of a hundred spikes "in full blow" can still stir the feelings of an old inhabitant who can remember the palmy days of the flower before the great frost of 1895. As Laurence wrote of Mr. Bradley when he first saw a bed of *Ranunculus* in a garden at Mitcham, my good old friend William Mauzer's "extasy was very great" when he saw this sight this autumn in a *Guernsey* garden, so much so that to let off steam he felt he had to write and tell me about it. I know the "extasy," too. Those visits to the lean-to house at Colesborne filled with the very best *Nerines* the world has ever seen! Can I ever forget them and their more than generous owner? They are among the red-letter days of my gardening life—never to be forgotten—on a par with the strange sight of the ninety-ninth Annual Gooseberry Show at Harborne and my first introduction to a Tulip Show and Feast at the floral metropolis of Middleton, near to which lies the little city of Manchester. We never know. The *Nerine* keeps itself to itself. I hope it never will allow itself to be spread out over the months as the *Carnation* has done. Somehow or other I do think Nature knew what mankind liked best when she ordained a certain season for each flower. The beauties that are here to-day and gone to-morrow are, I think, those that give us the greatest "extasy." If you have this feeling, you will know why the fatted calf was killed for the prodigal son. Just try *Nerines*! JOSEPH JACOB.

LARGE VARIETIES of PEARS FOR DESSERT or STEWING

Large specimen Pears are often useful to ornament the dinner-table (to say nothing of shop window display). They also find admirers visiting establishments during the shooting season, and often bring testimony to the skill of the cultivator. I remember many years ago the late Duke of Cambridge, visiting Sir Henry Ewart as a shooting guest, being greatly interested in some fine specimen fruits of General Todleben Pear, then hanging on the tree, and requested conversation with the writer as to how it was possible to produce Pears weighing over two pounds. I explained that I thought it might be the application, as a top-dressing, of sulphate of ammonia!

GENERAL TODLEBEN is a large long russety fruit, but rather difficult to ripen satisfactorily. Should climatic conditions favour its ripening, it may be claimed as good for dessert, although for my part I consider it much too large for that purpose; in fact, all fruits over 10 ozs. ought, so I consider, to be barred in competition in the dessert classes. The tree of this variety first produced fruit in 1855, and was named in honour of the gallant defender of Sebastopol. The flesh has a rosy tinge, is slightly gritty, with, however, plenty of juice, and, should the specimens be too large for dessert, its culinary value is well proved.

PITMASTON DUCHESS, also a Pear of immense size, was raised by a Mr. Williams of Pitmaston, near Worcester, some time about 1805. I have judged Pears of this variety in open competition over two pounds in weight, and often remarked, "Far too large for a pretty mouth." Seasons of sunshine will give finish and high flavour, and should no other Pear be handy, it will not altogether get condemned on the dessert dish. It thrives well whether trained as a cordon or espalier, or in bush form.

BLURRE CLAIRGEAU is a large and handsome fruit, the skin being smooth and shining, of a lemon colour, with a patch of orange red next the sun, covered with large russety dots and patches of thin delicate russet. The flesh is white, crisp, and in favourable seasons this is a good dessert Pear. It is ripe in November, and finds many admirers on account of its coloured appearance.

SOUVENIR DU CONGRES resembles a large Williams' Bon Chrétien, but is quite a distinct fruit none the less. The skin is bright yellow with cinnamon russet, and there are streaks of bright crimson on the side next the sun overlaid with russet. The flesh is yellowish white and juicy and of high flavour. It ripens at the end of August. It was raised at Lyon-Vaise, France, and introduced to commerce between 1865 and 1870. It is prolific on espalier, cordon, half-standard and bush, and finds a ready sale in the open market.

ROOSEVELT is a very large fruiting variety introduced about 1900, and I have seen enormous specimens of this Pear. As a variety it has two outstanding features, the one being its almost round, temple-like shape, and the other that every blossom has a double number of petals, namely, ten instead of five, giving the tree a charming appearance while in blossom. It is a noted cropper, and, during the past four seasons, the quality of production has been quite satisfactory. The fruit is green in colour with a slight flush, and to anyone requiring a constant bearer of large Pears, Roosevelt will answer the purpose. It ripens in October and is of fair quality. GEO. LOVLOCK.

Cotoneaster Simonsii.—Though a common species, often used for ornamental bedding, this is deserving of a warmer regard than it usually enjoys as a berrying shrub. It is a robust and easy doer almost anywhere, with a bold, somewhat stiff habit and a stature of some 10 ft. or more. The foliage, which is deciduous, or semi-evergreen, consists of rather rounded, oval-pointed leaves of a peculiarly fresh glossy green, and before these colour in autumn the large fruits assume a fine deep orange tint which changes to scarlet. These fruits are egg-shaped and borne in clusters of three or four, and as they are nearly $\frac{1}{2}$ in. long they make an effective display. On bushes occasionally cut back, or clipped hedges, the berries of *C. Simonsii* are produced on the older wood almost to the ground, as well as on that of the previous year's growth, so that a well berried specimen—and this species is most reliable in this respect—is a most attractive object. These berries, moreover, are seldom eaten by birds until most others have disappeared, and it is by no means uncommon to see a bush carrying its crop far into the winter. *C. Simonsii* is excellent for quickly covering a wall, and grown in this way it makes a useful support for choice Clematises and other climbing plants.

The Large White Meadow Saffron.—The large white Meadow Saffron, *Colchicum speciosum album*, has bloomed very well this season. It is exceedingly fine—much finer than the white variety of the ordinary *C. autumnale*. In size it far surpasses it, while in respect of its "staying" power in the way of resisting stormy weather, there can be no real comparison between the two, so immeasurably superior is *C. s. album*. It is of much greater substance and the tubes are so much stronger that it will stand up against weather which would render the smaller white one almost a wreck. Its colour, also, is purer, and for the rock garden or the front of the border it is superb. It does not appear as yet to have been planted largely in grass, but one can picture in the mind's eye the magnificent effect which would be produced by hundreds of this grand flower on such a carpet. It is as yet expensive, however, for such generous planting. As it increases quite freely in good soil, even a corm or two should prove a profitable investment. We owe this fine plant originally to Messrs. Backhouse of York, who sent it out, but its origin is unknown to us.

The Carnation in New Zealand.—In the Annual of the Hutt Valley (N.Z.) Horticultural Society there are a number of very interesting papers on various aspects of gardening in New Zealand, and it may be said at once that good garden practice appears to be much the same there as in the Old Country. A paper on the Cultivation of the Narcissus by that well known authority, Mr. A. E. Lowe, first attracted attention in this interesting little book, but Mr. Lowe's views on the question are fairly well known to readers of THE GARDEN. A paper on Border Carnations by Mr. H. A. Fox as they appear to a New Zealand enthusiast is of interest in several ways. Not only does Mr. Fox find no difficulty in importing plants from England, he actually finds that imported plants do better than native raised stock. He attributes this to the fact that, owing to the changing over of the seasons, the plants are seventeen months old when they come to flower. Mr. Fox imports from Mr. Douglas of Great Bookham, and he says: "My experience with Douglas's Carnations is that there are very few that burst. When they do it is caused by wind and sun hardening one side of the calyx with disastrous results. For this reason alone I always apply a rubber band to each bud just

before it shews colour. Directly the bud expands above the calyx the pressure is removed and the band can be slipped down and removed with scissors." A really excellent paper in an extremely interesting little book; one wishes it were obtainable in this country.

The First Issue of "The Garden."—A correspondent writes to say that he has a copy of the first issue of THE GARDEN (November 25, 1871) in good condition, which he would like to dispose of. If anyone reading this would like to acquire it, the Editor will gladly forward a letter.

FORTHCOMING EVENTS.

November 8.—Wargrave and District Gardeners' Society's Meeting.—Bedford and District Chrysanthemum Society's Exhibition.

November 9.—Gloucestershire Root and Fruit Society's Exhibition.

November 10.—Hawick Horticultural Society's Exhibition.

ANSWERS TO CORRESPONDENTS

So many of the Apples and Pears that are sent to this office for naming are unsuitable that we are constrained to point out (1) that fruit's should be ripe and typical of the variety; if the fruits seem to differ in type a good deal, it is better to send two or more fruits showing the different types; (2) the easiest way to mark the fruits is by marking a number upon the fruit itself in Roman figures with a sharp pencil—stump paper often becomes detached in transit; and (3) packing should be done very carefully, bearing in mind the present day Post Office methods of handling parcels in sacks. We endeavour to name all specimens sent, realising that in some cases typical specimens are not available, but in that case errors of identification are likely to occur.

FRUIT UNDER GLASS.

GRAPES UNSATISFACTORY (F. S.).—The Grapes have suffered from errors in cultivation, and are apparently ruined through insufficient or untimely ventilation. There is no specific disease apart from this.

KITCHEN GARDEN.

CELERY ATTACKED (R. N., Woodfield).—The Celery is attacked by the Celery leaf-spot disease due to the fungus *Septoria Petroselinii* var. *Api.* It is often carried over in diseased seed and all seed should be sterilised before sowing by steeping it for two hours in hydrogen peroxide. The diseased parts of plants should be completely burned.

MISCELLANEOUS.

HOW TO ESTABLISH MOSS UNDER TREES (Mlle. A. de S.).—It would be quite useless for our correspondent to attempt to grow any Moss on the ground while the roots of the Couch Grass are there. Ordinary grass, sown-growing, will kill Moss; Couch Grass will do so in much less time. The roots, or underground runners, should be taken out, then the surface rolled firmly, left so and not disturbed; and, if possible, it should be moistened occasionally. If any Moss can be procured but should be sown on the soil before the latter is rolled. Mosses drive on soils too poor to sustain the growth of grasses and, in northern aspects they spread rapidly. Failing to establish Moss, why not plant Heather? The ground would, of course, still need clearing of grass for this.

FUMIGATION WITH TOBACCO PAPER (C. H.).—Tobacco paper, as usually sold, will smoulder on lighting. Directions are generally given for its use by the vendor.

NAMES OF FRUITS—W. W., Porthshire.—Apples: 1, Golden Spire; 2, Warner's King.—C. V. B., Cornwall.—Apples: 1, Chatley's Kernel; 2, Barchard's Seedling; 3, Pope's Scarlet Costard; 4, Endleigh Beauty; 5, Washington. The specimens sent were exceptionally poor, thus making identification uncertain.

NAMES OF PLANTS—G. B., Anglesea.—1, *Tritonia crocosmeiflora*; 2, *Physalis capensis*; 3, *Fuchsia macrostemma globosa*; 4, *Salvia splendens*; 5 and 6, both garden hybrid *Fuchsias*. Cannot identify.—W. S. T., Norwich.—*Hibiscus Trionum*.—H. G. S.—*Centaurea rutifolia*. This plant is half hardy.—Mrs. S., Glos.—1, *Helenium autumnale purpureum*; 2, *Solidago canadensis*.

Do YOU know PARSONS'

WORCESTER BERRY ?

If not, you have yet to learn of one of
the most useful berries in cultivation ;

and WHY ?

It has **proved its worth** as a decided marvel
in berry-bearing fruits, viz. :

As a Cropper.

As a Jam or Jelly Fruit, or for Tarts.

As a resister of Big Bud (or Mite) and Mildew.

Owing to heavy demands I have only a limited quantity, but offer, as far as my stock will permit, as follows :

Bushes or Single Cordons .. 2/6 to 3/- each
Extra Strong Fruiting Bushes.. 3/6 to 5/- each
Double and Treble Cordons or
Fan Trained, for Walls,
Trellis, etc., Extra Strong
Fruiting .. 3/6 to 5/- each

Packing and Postage extra, viz. :

1 plant, 9d. ; 2 do., 1/- ; 3 do., 1/3 ; 4 do., 1/6 ; 6 or more,
carriage paid.

It has attracted enormous attention when exhibited at Shrewsbury, Harrogate, Glasgow and Edinburgh Shows, and the opinion of some hundreds who tasted it was "a delicious fruit."

If you have not seen above, ask for a copy of my New Fruit List FREE, with Coloured Plate of my Berry, Press Extracts, and Testimonials.

My List includes ALL THE BEST in APPLES, PEARS, PLUMS, etc., and my Worcester Crown FIBROUS-ROOTED Trees may be relied upon for BEST RESULTS and QUICK RETURNS.

[NOVEMBER 10, 1923.]

TREES AND SHRUBS FOR FOLIAGE

THERE are many trees and shrubs which are worth a place in gardens for their foliage and habit of growth. Some of them, indeed, have no other merit—the Bamboos, for example. A great deal of the beauty to be obtained by such planting depends upon proper grouping, sometimes merely of the species in question, but more frequently as regards its placing among other trees and shrubs of a character and habit of growth calculated to shew it up to best advantage.

The Bamboos have been mentioned as examples of shrubs which are cultivated solely for their foliage and habit of growth, but, unless used with the greatest care and in suitable situations, most of the species can scarcely be called attractive. An exception must, however, be made in favour of *Bambusa pumila*, which, though apt to spread almost too freely, is one of the very best plants we have for "carpeting" in shrubbery or wild garden. The foliage is of a delightful green colour very pleasant to the eye. Another plant grown entirely for its handsome pinnate foliage is the Tree of Heaven, *Ailanthus glandulosa*, which, remarkable and beautiful throughout the growing season, is especially attractive when the foliage takes on a mellow golden tint preparatory to the fall. The new *A. Vilmoriniana* has even larger foliage. The Sumachs, with somewhat similar pinnate leafage and more brilliant autumn colouring, have the added attraction of the curious rather candelabra-like inflorescences.

Several Araliads have very handsome foliage, notably the Chinese Angelica tree (*Aralia chinensis*), and the very similar *A. spinosa*, the so-called *Aralia Sieboldii*—more properly *Fatsia japonica*—and several members of the genus *Acanthopanax*. The most striking of these is *A. richii-folium* (*Aralia Maximowiczii*) with leaves on young plants 1 ft. or 15 ins. across, but *AA. Henryi*, *lencorrhizum*, *pentaphyllum*, *senticosum*, *sessiliflorum* and *sutchuenense* are all handsome and remarkable in their appearance. Some of them are very attractive when bearing their quantities of ivy-like berries. All the Tree Ivies—merely fruiting forms of

the several species—have attractive foliage, and at least one species—*Hedera colchica* (better known as *Ragneriana*)—is remarkable in the climbing (non-fruited) form. The Araliads, however, have an appearance so very distinctive and exotic that they should either be used boldly to create an atmosphere or neglected altogether. A single specimen or group in a mixed shrubbery is apt to look very spotty and bizarre.

The great Maple family is noteworthy for its beautiful foliage, and many gardeners would consider that the Japanese varieties of *Acer*

palmatum (in particular) and *A. japonicum* hold the palm for beauty of leafage. Certainly they are very attractive and, for a small garden, well-nigh indispensable, yet here again the exotic appearance of many of the varieties is noteworthy, and they should be used fairly extensively in any planting in which they are employed, and not scattered indiscriminately over the whole garden. Moreover, they should have shelter from the north and east. The varieties are almost all attractive, but some are not very robust. A list of the very best would include *A. palmatum* (type) and vars. *aureum*, *septemlobum atropurpureum*, *s. elegans*, *s. reticulatum*, *s. sanguineum*, *dissectum*, *d. rubrum*, *d. purpureum* and *sessilifolium*, with *A. japonicum* (type) and vars. *aureum* and *filicifolium*.

The Box Elders, forms of *Acer Negundo*, have also remarkable and attractive foliage. The typical plant grows into a not unattractive tree of some size, but the variegated forms called *variegatum* and *aureo-marginata* are more generally grown. Of the two, *aureo-marginata* is the more vigorous. Variety *aureum* (syn. *odessanum*) has leaves entirely golden, and is a free grower, but not very attractive.

Most of the taller Maples and Sycamores have handsome foliage, though few, if any, are more beautiful than the Common Maple of our hedgerows, *A. campestre*. Two other species which appeal rather specially to the writer may be mentioned, namely, *AA. circinatum* (the Vine Maple), of rather a low spreading habit of growth, and the purplish foliaged form of the Norway Maple known as *A. platanoides Schwedleri*; but many others of equal merit might be selected.

Among Barberries, those most effective as foliage shrubs, are, as a rule, by no means the most brilliant when in flower, though no one could call the foliage of those old favourites, *Berberis Darwinii* and *B. stenophylla*, anything but beautiful. They have not, however, the striking appearance when out of flower which is characteristic of *BB. aristata* and *Hookeri*. Neither of these species, however, compares as regards sheer beauty of

AUTUMNAL SPRAYS OF VIBURNUM OPULUS FRUCTU-LUTEO.

the most beautiful of the *Malvaceae*, *B. Aquinifolia*, etc., especially the *Malvaceae* of *B. japonica*, such as *B. Thunbergii*, etc., extra large foliage, and *B. Thunbergii*, etc.

The most beautiful of the gigantic foliage are, for the most part, *Malvaceae*, *Gunnera*, *Rheum*, etc. But the most hard back each spring, *Paulownia japonica*, makes tremendous growth and will, after feeding, produce leaves 2 ft. to 3 ft. across. This tree is not a great success except in our milder districts and, even there, it does not as a rule flower freely; but plants for cutting back in the way described may, with little difficulty, be given protection in hard weather.

The most characteristic and perhaps the most beautiful of British trees is the Oak, but there is nothing specially attractive—at least as growing—about its foliage, but a few exotic species and varieties, notably *Quercus pedunculata* and *Q. rubra* and *velutina rubrifolia*, have very large and handsome foliage. The Scarlet American Oak, *Q. coccinea*, so well known for its autumn colour, also has large, rather handsome foliage.

The foliage of the Tulip Tree, *Liriodendron tulipifera*, attracts because of its size, and also because of its unusual and rather peculiar "saddle" shape. The foliage takes on, in autumn, a rich but mellow yellow colouring very much like that of the *Ailanthus*. Another tree with unusual and handsome foliage is the well named Maidenhair Tree, *Ginkgo biloba*, which also colours pleasantly.

The Service Tree, *Pyrus Sorbus*, is noteworthy for its handsome foliage, and all the members of its family, including the Mountain Ash, *Pyrus Aucuparia*, to some extent share its distinction. The Locust, *Robinia Pseudacacia*, has very beautiful graceful foliage, and so have most of its sister species, but it is scarcely improved by the hard pruning so often given to these trees, which makes for congestion of growth, though the brittleness of the wood to some extent justifies the treatment. Somewhat similar is the foliage of the beautiful but not very hardy *Gleditsias*.

The beautiful foliage of many Vines is noteworthy. An article on these very handsome and useful plants has appeared recently, so that there is no need now to dwell upon them. The most useful species of all is *V. Coccinea*. The reddish foliage of *Clematis montana rubens* is very handsome and distinctive, though it has not the exotic magnificence of the evergreen *Clematis Armandi*, which does not look hardy and, alas! is not, except in favoured situations.

The *Escallomias* are noteworthy for beautiful foliage. Perhaps the best of them in this respect is *E. mariantha*, which, moreover, is one of the trees to flower, being scarcely ever without blossom. The foliage of the Cherries colours nicely in autumn, but is otherwise, as a rule, without special interest. An exception is the Japanese Cherry New Red, with leaves of a delightful bronzy shade, which shows up the structure of the leaf to great advantage.

The gigantic foliage of some of the new Asiatic *Rhododendrons* is perhaps more remarkable than beautiful, but that of *R. orbiculare* may pass muster on the grounds alike of interest and beauty. The same may be said of many of the deciduous species, but perhaps *R. flavum* (*Azalea pontica*) is the palm in this respect. It colours well in autumn, too, and has passed on a great deal of its beautiful leaf character to the Ghent *Azaleas*, of which it is one of the principal parents.

The Loquat, *Eriobotrya japonica* is known to many of us for its exceedingly palatable though very seedy fruit, but only in exceptional summers does it ripen fruit in this country. Merely as a beautiful foliage tree, however, it is worth growing, and is well deserving of the shelter of a wall, which, in cold districts, it needs.

THE SPLENDID FOLIAGE OF *BERBERIS JAPONICA*.

THE HANDSOME, BUT RATHER TENDER, LOQUAT, *ERIOBOTRYA JAPONICA*.

A YOUNG PLANT OF *AILANTHUS VILMORINIANA*.

WIND-SWEPT SEASIDE GARDENS

Some Suggestions for Providing Shelter.

IN the majority of English gardens near the sea, lack of shelter from wind neutralises the advantage that might be obtained from the mildness of climate. How many a seaside garden, almost free from frost, but swept by wind, looks so bleak as to make one long for the up-country garden "bosomed high in tufted trees." What can be grown on a coast such as that of Dorset, provided that wind shelter can be arranged, may be seen in the famous garden at Abbotsbury, where screens of *Ilex* have made possible a wonderful expansion of the gardener's repertory. There, in little more than a single decade, a seedling of *Acacia dealbata* will race up into the beauty of a great tree, and *Magnolia Campbellii* can open its incomparable rose-pink flowers unhurt. Of course, not one in many a thousand of seaside gardeners has the chance of making an Abbotsbury; but much more could be done in the way of making seaside gardens bearable if the repertory of wind-resisting plants and the technique of growing them were more widely known. Here are some notes by one who is gardening under these conditions; they are written chiefly with the hope that they may provoke others to an exchange of experiences, or be of some use, slight as they are, to some fellow-experimenter.

Pinus insignis, the Californian Pine, shall come first. There seems to be general agreement among those who have experimented that this is the best windscreen of all its tribe, in a mild climate. It grows very fast and is apt to get blown over at about ten years of age unless it has some shelter or is topped, and in salt-laden gales the outside trees of a plantation often get seared brown for a time. But with reasonable care it can be grown into a splendid tree where nothing else of its stature would survive. The wood of it in the Scillies is a sight to remember—a dark, whispering forest away there in the midst of the Atlantic. And in the Land's End peninsula, even on such exposed sites as St. Michael's Mount, it is making splendid growth. Huge trees in the gardens near Penzance were planted as seedlings only thirty years ago.

P. insignis is easily raised from seed, but such good plants can be bought for 18s. a dozen (e.g., from Treseder at Truro), that, except for extensive plantations, seed-raising is hardly worth troubling about. The plants should not be more than about 2ft. high at planting time; they should be taken from pots, or well balled in hessian for moving, as they are impatient of disturbance. Like *Eucalyptus Globulus* they are great robbers of the soil. *Cupressus macrocarpa*, the Pine's neighbour at Monterey, seems to be less satisfactory as a full-sized tree; where the Cypress has been planted in a belt for shelter, one often sees gaps owing to uprooting. But as a tall hedge, kept properly topped, the Cypress is certainly most valuable. Like the Pine it will not stand careless transplanting. *Quercus Ilex*, again, is notoriously impatient of moving. It is best put out from pots at, I think, the end of April. Opinions vary as to its value as a seaside tree; at Abbotsbury it seems to be the chief standby, whereas I have heard some Cornish gardeners disparage it. Certainly it has a tiresomely untidy way of shedding its leaves which makes it unsuitable for positions where regular sweeping would be required. For beauty of form few trees, I think, can equal the *Ilex*. I call to mind a little thicket of it, underplanted with Crocuses, in a coomb near the Lizard; with their

narrow twisted trunks and wind-cropt heads they are very different in character from the huge *Ilex* masses that hang out from the cliffs of Lake Nemi, but hardly less beautiful.

So much for the three best known trees for seaside planting. I will not stop to deal with the Austrian Pine and others of its tribe, or with such as the Cornish Elm, but will hurry on to my favourite, *Pittosporum crassifolium*. Why is it that nurserymen are still so short of stock of this invaluable plant, probably the finest of all wind-screens of moderate size for a wind garden? *Escallonia macrantha* is splendid, of course, beautiful in flower and leaf and rapid in growth.

plant the long, narrow leaves of *crassifolium*, dull grey green against the pale glaucous leafbuds, the larger size of the maroon-crimson flowers and green seed capsules, and above all the much more erect habit of the shrub, are enough to distinguish the two plants at a glance. Other *Pittosporums* of great value for seaside hedges include *tenuifolium*, with scented flowers, and the well known *P. Tobira*.

Another beautiful grey-leaved shrub, or rather a tree, is *Olearia Traversii*. This has been referred to in these columns as having proved hardy on the East Coast of Scotland, but I gather that other growers, even on the South Coast of England, have

CORDYLINAE AUSTRALIS, VERY EXOTIC IN APPEARANCE, LOOKS BETTER WHEN PLANTED IN FAIR QUANTITY.

But, unlike the *Pittosporum*, it is a robber of a wide area of soil, it dies badly in the middle if neglected, and in salty gales its leaves often get burnt. How it compares with the *Pittosporum* in resistance to frost I do not know; certainly there are gardens, even in Cornwall, where the *Escallonia* gets cut by frost quite often. The *Pittosporum* has a lovely glaucous colour and rare distinction of form both in leaf and fruit. It stands the first shock of the sea wind and makes a splendid upright hedge here, as in New Zealand (where it is extensively used for this purpose).

The plant bears plenty of fertile seed (unlike *P. Fairchildii*), and is easily raised, but I have found difficulty in buying it true to name. *P. Ralphii* and even the very dissimilar *P. Buchananii* have been sent under this name. The confusion with *P. Ralphii* is worth clearing up, for *crassifolium* is undoubtedly the more valuable plant of the two. In the seedling stage the two are very much alike, but about a year's growth is sufficient to distinguish them easily. *Ralphii* is the greener, softer plant, the leaves of *crassifolium* being already harder and thicker, whitish underneath and shewing a white margin on their upper side. In the maturer

had a different experience. The plant grows extremely fast and though it must stand a lot of wind in its home on Chatham Island, may, some tell me, prove too shallow a rooter for the windiest exposures, though, so far I have not found this. It has no beauty of flower, but the white undersides of the leaves and the plant's delightful trim appearance of good health and vigour, make it very well worth trying in seaside gardens where such trees are wanted.

I believe *Olearia oleaefolia*, which was strongly recommended as a seaside plant by that great expert, the late Mr. T. Smith of Newry, will prove even more valuable. It has the merit of making a show of white flowers in the autumn, and the tough greyish leaves are pleasant and obviously well suited for withstanding wind. There is a beautiful photograph of a bush of it in flower in the Royal Horticultural Society's Journal of January of this year. *O. macrodonta*, much better known, is, of course, a splendid coast shrub, rapid in growth and free in flower; indeed, all the *Olearias* I have tried will stand a great deal of wind. The most beautiful of all, *O. semidentata*, does not turn a hair here, even in the worst of gales. Many

found difficult with this plant. It has a habit of suddenly becoming very large. But it may be used in leaf or in flower as it grows on grey rocks or in a towering clump of palings in a certain famous garden. All want to have a try with it. It is a daisy in its setting of leaves, and has a rare discreet beauty of colour. It likes some shade. The grey-leaved *Sedums*, which make good company for the *Oleas*, are, of course, well known as wind-sisters. *S. compacta* is, I think, even more useful than *S. Gravin*.

For a really wild seaside climate there can hardly be a tree more splendid than *Metrosideros lucida* and its ally in robusta. (Can anyone help me, by the way, to obtain the tree form of *M. lucida*? I have only got the bushy variety.) There must be many gardens on the South Coast where these would grow and flower as freely as they do in this neighbourhood (West Cornwall), and where their myrtle-like leaves and wealth of crimson-scarlet flowers in July would be an outstanding feature. Perhaps even the great tree, *M. tomentosa*, will be found to thrive in some gardens on the mainland as it does in the Scillies. Young plants have already stood two winters here and made much growth, but these have been mild winters; now that they have made mature leaves and some hard wood I believe they will survive; in most places the best chance would be to grow them on in pots or tubs till they are mature.

Griselinia littoralis has been recommended as capable of withstanding the first shock of Atlantic gales. This has not been my experience, but I admit that I subjected the plants to an exceptionally severe ordeal. Probably they would be all right if planted close together and given some shelter at the start. They are certainly useful for such purposes as stopping gaps inside the defences, but they have no beauty of flower, and though handsome and healthy in colour when the leaves have reached the adult stage, these are rather sour and yellow green when young. It is well known that *Cordyline australis* will stand a terrific blast, and the scent of its flowers is so pervading and delicious that it predominates over all other recollections of some seaside gardens in summer. Unfortunately, the "Palms and Pricklies," the plants commonly classified as "sub-tropical," are seldom happily placed; more often than not *Cordyline* is grown almost solitary in some context where its exotic character is not pleasantly but uncomfortably apparent. Grown in some quantity, say, in a little avenue up a drive, it is capable of splendid effect.

Here, in conclusion, are some of the plants which will stand a lot of wind, not on the outer rampart, but in the wind-swept places within the first line of defence:—

Cytisus fragrans (will stand far more than one would expect); *Hydrangea hortensis*, of course (indeed this will even stand the full gale, *H. paniculata* is much less resistant); *Berberis Darwinii* (will grow in the teeth of the gale, but, unless it has shelter, its flowers get cut to pieces); *Tricuspidaria lanceolata*; *Destonainea spinosa*; *Correa virens* (tender), and, I think, *C. Harrisi*, etc.; *Abutilon vitifolium*; *Clethra arborea* (tender, stands more than one would expect, more, I think, than *Arbutus*). Or *Vernonia*, the well known Blue Gem is a common but most valuable plant and will stand the full gale, but all the nearly all the others are less wind-hardy. The red sorts are magnificent in colour. The *Heaths*; *Rosemary*; *Lavender*, of course. *Leptospermum*: I am not yet sure how much these will stand. *L. Boissaweni* is certainly liable to be injured by a salt gale, but the others seem harder. Of the *Heaths*, *E. arborea* and *E. Veitchii* will stand a lot; *E. codonodes* gets its

flowers browned in bad weather; *E. melanthera*, certainly, and, I think, *E. australis*, will not stand any severe exposure. The *Epacris*, where they can be grown outside, seem very wind-hardy, and *E. magnifica* should certainly be tried in mild windy gardens; *Launuma apiculata*. —

But it is time I stopped. One last word; 600ft. up, facing the north-wester's first onslaught from the Atlantic, is good old *Rhododendron ponticum*; it even manages to flower profusely. Can anyone tell me what other *Rhododendrons* are fairly wind-hardy? Z.

PYRUSES of the AUCUPARIA SECTION

THOUGH perhaps, as flowering trees, rather overshadowed by the glorious masses of blossoms produced by the *Malus* (Crab) section of the genus, there are very many beautiful trees among the Mountain Ashes or pinnate-leaved *Sorbi*.

As regards foliage, the species and varieties of the *Aucuparia* section easily lead, but they must take a back seat to the Flowering Crabs during May and early June. If only the birds would leave the fruits alone in autumn, some of the Mountain Ashes would be near the top of the poll, were a referendum to be taken among tree lovers. Heavily laden as they generally are with richly coloured fruits, we are able to admire their beauty during the ripening period. When the fruits attain maturity they are not, however, long safe from birds in most seasons; unless, indeed, the trees are growing in small town or suburban gardens, where they sometimes escape attention from our feathered friends.

Little need be said regarding the soil for these trees. They thrive in most soils, which, to get the best results, should be trenched and manured. A loamy soil of a calcareous nature is generally recommended for planting, but is far from essential, judging by the way the *Sorbi* grow and fruit in the sandy medium, deficient in lime, at Kew.

Increase is by seeds, grafting and budding. Do not harvest and store the seeds (pips) dry. Place them when taken from the fruits in damp sand or sandy soil. Propagation by this means is only recommended for the species. Even among these, if it happens to be a good form, increase by grafting or budding is preferable, as seedlings do not always come true. Some may be an improvement on the parent, but if this represented a very good selection, the probability is that the majority will be inferior.

For this reason cultivators prefer to do most of their multiplication of species and varieties by vegetative means. Seedlings of *Pyrus Aucuparia* make a very good stock, the trees being hardy, free in growth, and not particular regarding soil.

I have noticed from time to time a number of the species and varieties developing shoots of *Thorn* (*Crataegus*) from the stock, and have been

told that this is a favourite stock in some of the Continental nurseries. The growth and general health of the trees suggests that it is a happy union and we know that the *Thorns* are trees easily accommodated in the matter of soil.

For planting in the pleasure grounds the newer Chinese species are very valuable and distinct additions. In the park and open woodland the varieties of *Pyrus Aucuparia* and *P. Sorbus* possess attractions in foliage, flower, fruit and autumn colouring which make them of interest in the landscape.

The best known and one of the most generally planted species is *Pyrus* (*Sorbus*) *Aucuparia*, the Mountain Ash or Rowan. It is a useful tree for small gardens, though it ultimately attains a height of from 30ft. to 50ft. The pinnate leaves are ornamental throughout the summer. During May the flat heads of white flowers attract attention, these being followed in August and September by clusters of very showy coral-red fruits.

For garden planting there are several forms or varieties even more attractive than the native and typical species. The best of these are var. *moravica*, the Moravian Mountain Ash, a wild tree of Northern Austria, with rich red fruits double the size of the type. The fern-leaved variety—*asplenifolia*, has

FRUITS OF THE DAINTY PYRUS VILMORINI.

the segments of the leaves deeply cut, a pretty contrast to the foliage of other trees. The variety *Backhousei* is rather more upright in growth and produces bright red fruits very freely, while *fructu-luteo*, as the name suggests, has bright yellow berries. The stiff upright habit of *var. fastigiata* is very distinct and the plant is valuable for confined areas. The autumn tints of Mountain Ash leaves are very beautiful, the golden yellow colour of *var. fructu-luteo* in particular.

A fairly common tree, often a bush, in mountainous districts of Britain, the Mountain Ash has also a wide distribution in Europe and the temperate regions of Asia.

We have two Service Trees, *P. Sorbus* (*Sorbus domestica*), the True Service Tree, and the Wild Service Tree, *P. Torminalis* (*Sorbus Torminalis*). These common names were evidently given to indicate the fact that *P. Torminalis* is a native of Britain, while there is only one instance of a solitary tree of *P. Sorbus* in this country growing quite away from cultivated areas. This was a very old tree in Wyre Forest near Bewdly, known for two hundred years, but destroyed in 1862. Possibly this was a garden escape, the fruit having been carried by a bird.

P. Sorbus is a native of Southern and Eastern Europe. Growing as an isolated specimen it is an attractive foliage tree. In "The Trees of Great Britain and Ireland" by Elwes and Henry, they record a tree in Kilkenny, Ireland, 77ft. in height, with a girth of 10ft. 8ins. The panicles of white flowers are freely produced in May; they are not quite so wide as the Mountain Ash, but the individual flowers are larger, $\frac{1}{2}$ in. across.

There are two forms of the True Service Tree: *var. maliformis* with round or apple-shaped fruits, and *var. pyriformis*, perhaps the better known tree, having pear-shaped fruits. In autumn, a sheen of crimson bronze on the pinnate leaves before they fall is very beautiful.

P. AMERICANA.—The American Mountain Ash is a tree 15ft. to 30ft. high, resembling somewhat our native species, but with larger leaves. The creamy-white flowers are borne in flattish cymes 3ins. to 4ins. across, followed by rich red fruits.

P. CONRADINÆ is one of the new Chinese Sorbi, introduced by Mr. E. H. Wilson from Western Szechuen in 1908. It is an attractive pinnate-leaved tree 18ft. to 25ft. high. The leaves are dark green above, white or greyish-white beneath. The white corymbs of flowers are 2 $\frac{1}{2}$ ins. to 4ins. across, the fruits orange-red. This tree is No. 1015 of Mr. Wilson's 1908 expedition.

P. GLOMERULATA was discovered in and introduced by Mr. Wilson from Western Hupeh in 1907. It promises to grow into an attractive small tree or large bush having pinnate leaves some 3ins. to 5ins. long, corymbs of white flowers and pearly-white fruits. In foliage, but particularly in fruit, this Chinese Sorbus is a valuable addition to the family, the only trouble is that, unless netted, the fruits are soon cleared by the blackbirds and thrushes. Wilson's numbers for this species are 1494 and 3001. When first introduced it was confused with *P. KÖHNENIANA*, also a white-fruited species, but with smaller leaves and pinnæ and also botanical differences. The latter is evidently a much more widely distributed bush or small tree in a wild state, as specimens were collected by at least four travellers—Messrs. Giraldi, Henry, Purdom and Wilson—in Southern Shensi and Western Hupeh between 1894 and 1910.

P. MUNDA VAR. SUBARACHNOIDEA is the best known of the newer Chinese Sorbi, largely because of the attractive sprays exhibited at several of the fortnightly meetings of the Royal Horticultural Society by the Hon. Vicary Gibbs. These shew it to be a very free-fruited tree at Aldenham. To bring such sprays of fruits to Vincent Square

the trees are probably netted, for the birds seem as partial, or more so, to the pearly-white fruits of these Chinese trees as they are to the common Mountain Ash. In China it is found as a bush or small tree up to about 20ft. high. Mr. Wilson collected it in Western Szechuen in 1910 at 7,000ft. to 9,000ft., this being Wilson's No. 4323.

P. VILMORINI is a small tree or bush of graceful appearance. In spring the elegant pinnate leaves unfold, soon followed by corymbs of white flowers during June. In autumn the rosy-red fruits claim

attention. This *Sorbus* was introduced to France by Père Delavay in 1880, and was grown by Mr. Maurice de Vilmorin and first fruited in his well known garden at Verrières. This Chinese species has been confused with the Himalayan *P. foliolosa*, being named *Sorbus foliolosa*, Franchet. Herbarium specimens of *P. foliolosa*, Wallich., collected in Sikkim by the late Mr. C. B. Clarke in 1884, suggest that it is quite distinct from Delavay's plant, the leaves being very woolly on the underside and altogether heavier-looking. A. O.

PROPAGATION OF HERBACEOUS PLANTS BY ROOT-CUTTINGS

HARDY herbaceous plants may be propagated by various methods, the most natural and efficient being by means of seeds. In nature, plants spread by means of seeds. Some are carried by wind far from the parent plants by

by means of cuttings, that is, parts of the plant, either stems or roots, severed from the parent and inserted in soil so that they root and make new plants.

In this article, however, we are only concerned in the method of reproducing plants by means

THE BEAUTIFUL *ANCHUSA ITALICA*, DROPMORE VARIETY, WHICH IS PROPAGATED BY ROOT-CUTTINGS.

means of wings, as in the Maple and Ash; others are floated by means of down or plumes, as in the Thistle, Dandelion and many other members of the Composite Order. Some seeds, like those of the Squirting Cucumber, are ejected forcibly to a considerable distance from their capsules. It is not, however, by seeds alone that plants multiply themselves. Many kinds reproduce themselves by means of runners, like the Strawberry; while others increase by means of underground stems, like the Couch Grass. The offsets of House-leeks (*Sempervivum*) and Sedums detach easily and form new plants. The bulblets on the stems of some of the Liliaceae and Alliaceae, as well as the leafy tufts on the fronds of certain Ferns are all capable of reproducing the parent plant under favourable conditions.

The above are some instances of Nature's methods of propagation, but plants may be increased in various other ways. One of the most common is by means of division of the rootstock in the autumn or spring. Grafting and budding as a means of increase is confined mostly to trees and shrubs. Then we have propagation

of root cuttings, a method which is adopted largely in the case of certain kinds. Many species can, in fact, be increased rapidly by means of short cuttings of the roots, especially those species which have a natural tendency to "sucker" or send up shoots from the root. Rootstocks or underground stems may be made into cuttings, but true root-cuttings possess no buds till these develop after planting. Among kitchen-garden plants the Horse-radish is the most familiar example of propagation by means of root cuttings. The small side roots, $\frac{1}{2}$ in. or so in diameter, are taken off when the Horse-radish is dug in the autumn or spring and are cut into lengths of about 4ins. In the spring these "sets," as they are called, are planted in rows 2ins. to 4ins. deep in deeply trenched ground to produce another crop of roots.

Many other plants lend themselves to this manner of increase, notably those of the Borage family, *Anchusas* and *Symphytum*, among others. All those with large enough roots can be treated in the same way as the Horse-radish, planted out in rows in the nursery but it is

necessary to surround the cuttings of some kinds with sand to prevent rotting. Some gardeners insert the root cuttings in boxes or pans of soil, keep them in a cool place till the roots callus, and then introduce them to a little heat to start them into growth. When hardened off again they are planted out in the nursery to develop. Plants with smaller roots, like those of *Morisia*, are best kept in pans of sandy soil till they start growing, when they can be potted off separately. Among plants that can be increased in this

way are *Acanthus* (Bear's Breach), *Anchusa italica* and others, *Anemone japonica*, *Arnica* or *Macrotomia echinoides*, *Bocconia cordata*, *Chicory* (*Cichorium Intybus*), Sea Kale (*Crambe maritima* and other species), Dandelion (*Taraxacum officinale*), *Gaillardias*, Horse-radish (*Cochlearia Armoracia*), *Mandragora* (Mandrake), *Mertensia*, *Nicotiana affinis*, *Ostrowskia magnifica*, *Papaver orientale* (best under glass in sand in autumn), *Polygonum* (various), *Romneya Coulteri*, *Rubia peregrina*, *Tragopogon pterifolius* (Salsola).

Silphium (various species), *Verbascum nigrum* and *Senecio pulcher*.

In addition to the above, no doubt, many other plants would respond to this method of increase. Experiments are now being carried out dealing with the plants of many families. The main essential is that the root must be thick and fleshy enough to subsist till the end forms a callus; after which, in the natural process, a bud is formed and, under favourable conditions, a new plant is developed. W. I.

THE FORTNIGHTLY MEETING OF THE ROYAL HORTICULTURAL SOCIETY

IT was "Orchid Day" at Vincent Square on October 30, when the two-day meeting of the Royal Horticultural Society opened, for fully one-half of the Hall was devoted to these fascinating flowers, and there was a special competition for them. As this and the corresponding meetings each year are largely set aside for Orchids, all the principal amateur and trade growers meet in friendly rivalry, and it is a pleasant thing to be able to record that in the Orchid world the amateurs quite hold their own. A gold medal was awarded to Mr. Pantia Ralli, Ashted Park, for a most delightfully arranged group of beautiful and gorgeous Orchids. The association of the fascinating Blue Orchids (*Vanda coerulea*) with the long, arching sprays of the yellow *Oncidiums* (*O. varicosum Rogerii* and *O. Marshallianum*) charmed many of the visitors. In another portion the massed purples and mauves of various *Cattleyas* were relieved and enhanced by the purity of *Cattleya labiata alba* The Sultan. There were very many specimen plants of great merit. *Brasso-Cattleya Olympus* was a magnificent plant bearing a spike of four large and exquisite blooms. *Lalio-Cattleya Honoria* was also a most delightful plant. The irregular row of many plants of the green and white *Cypripedium Maudie* was a charming finish to the group.

Around the corner Messrs. Sander and Co. also had a gold medal group, and this contained what must have been a record number of Blue Orchids. Besides the type plant they had *Vanda Sapphire* of a more substantial shade of blue and a great many plants of *V. Blue Boy*, much of the colour of the sky when the blue is flaked and teamed with white fleecy clouds. Besides a great many of the decorative Orchids—the *Cattleyas*, *Odontoglossums*, *Oncidiums*, *Cymbidiums* and so on—Messrs. Sander had an interesting collection of the botanical species, including the wend *Masdevallia Wallisi* stupenda.

Another gold medal was deservedly awarded to Messrs. J. and A. McBean for a large collection of excellent plants. Here there were many examples of the type of *Cattleya* which bears flowers of a startling combination of golden petals and vividly coloured

lips, varied by others of crimson and pale orange or fierce cardinal red and citron. *Cattleya Aeneas*, with deep golden, fawn-tipped petals and beautifully waved crimson lip, was another strikingly handsome flower.

Baron Schröder sent from The Dell, Englefield Green, one of his famous exhibits, which won the Orchid Cup. Several masses of *Cattleya Bowringiana* and its varieties received an immense amount of admiration on account of the gorgeous rich rose pink colour of the flowers. These are small for *Cattleyas*, but are produced in unusual numbers and are of dendrobium-like appearance. The *Calanthes* and *Odontoglossums* in this collection were also superb.

Besides the trade groups already mentioned, fine exhibits were made by Messrs. Charlesworth and Co., Messrs. Cowan and Co., Messrs. Mansell and Hatcher, Messrs. Cypher and Co., Messrs. Flory and Black and Mr. H. Dixon, who all had excellent plants and in great variety. The Butterfly Orchid (*Oncidium Papilio*), the pansy-like *Miltonias*, the graceful *Odontoglossums* and the vivid colouring of the *Sophranochilus* were all of immense value.

The general floral exhibits included a splendid collection of stove plants well set out by Messrs. L. R. Russell, Limited, and, beautiful as this was in the morning, the rich colours of the *Crotons* and *Dracenas* were even more effective under

artificial light later in the day. One plant of the interesting "Pitcher Plant" had a hanging pitcher over a foot long. The richly coloured flowers of *Passiflora princeps* were also very uncommon.

A good collection of *Nerines* was sent from Colesborne by Colonel H. C. Elwes, D.S.O., and the delicately beautiful colours of the flowers was enhanced by the coral red of the *Berberis* sprays, which were lightly laid beneath these Guernsey Lilies.

In anticipation of the Show on Thursday, *Chrysanthemums* were prominent. Mr. H. J. Jones had an imposing collection of large exhibition blooms with the smaller singles as market types. Messrs. Keith Luxford and Co., Mr. H. Yandell, Messrs. Carter Page and Co. and Messrs. W. J. Godfrey and Son shewed good collections of decorative sprays.

A new, or at any rate infrequent, exhibitor at the meetings is Mrs. Sofer Whitbourn, Ampport St. Mary's, Andover, who sent excellent plants of winter-flowering *Begonias*. Even after the long journey the plants were admirable.

Carnations, Roses and a few collections of border flowers all added variety to an interesting Show.

Fruit and vegetables were more freely shewn than is usual at the fortnightly meetings, but even more collections would be welcomed. Messrs.

THE NEW CORAL-FRUITED *BERBERIS* "COMET".

Barr and Sons had a general collection of seasonable vegetables set out in the best exhibition manner. The Celery, Leeks, Carrots, and Salsafy were all of superb quality, while the several varieties of Onions, Tomatoes, Artichokes, Kales and *Stachys tuberosa* added variety. The delicate, yet bright colours of the Peachblow and Golden Sunrise Tomatoes were much admired, while more brightness was provided by the stems of the Chilian Beet, which were as vividly coloured as forced Rhubarb.

Messrs. Sutton and Sons displayed an imposing collection of Brassicas. The dignified method of arrangement added to the value of the exhibit, which in itself was of great merit. Among the Red Cabbages were Blood Red and Selected Blood Red. The Savoy included Best of All, Perfection, Reliance and Green Curled; while the chief green Cabbages were Maincrop, Favourite, Little Gem and Colewort.

A splendid collection of Apples was arranged by Mr. E. J. Parson. He had gorgeously coloured dishes of Worcester Pearmain and William Crump, and also ideal fruits of Lord Hindlip and Newton Wonder with many other valuable sorts. Mr. W. Lane sent eight dishes of good Apples, and Mr. Jaspar Davis, Chippenham, shewed half a dozen dishes of well grown Potatoes.

From Devizes Castle, Wiltshire, Mrs. Reid sent a superb collection of dessert fruit which was very attractively arranged. The large shapely bunches of well finished Grapes included Muscat of Alexandria and Black Alicante. Among a number of Apples of ideal size there was a dish of magnificent Pitnaston Duchess Pears.

NEW AND RARE PLANTS.

Berberis Comet.—It was said by some that this new Barberry fruited even too freely, as this profusion gave the branchlets a congested appearance and also made them seem stiff; that with fewer fruits the branchlets would arch gracefully. Be that as it may, it is a good fault and the bright coral colour was gorgeously attractive. Award of merit. Shewn by the Royal Horticultural Society.

Buddleia auriculata.—A quite uncommon shrub which produces long, graceful branches set with horizontal twigs. The lanceolate leaves are green above and silvery beneath, and on the specimens on view the undersides of the leaves were rather prominent, giving a silvery appearance. The free, terminal clusters were composed of small, pinkish fragrant flowers which have green tubes. If this species proves to be hardy, which we understand is likely, it will be worthy of extensive planting. Award of merit. Shewn by the Director, Royal Gardens, Kew.

Chrysanthemum Exmouth Pink.—A medium-sized, single-flowered variety of good type and bright rose pink colour. The florets are substantial and the blooms travel well. Award of merit. Shewn by Messrs. W. J. Godfrey and Son.

C. Golden Marvel.—A market-sized Japanese variety of substantial flattish shape and golden orange colour. Award of merit.

C. Mrs. E. Reeves.—A good Decorative variety with narrow golden yellow florets, slightly curled. An attractive and stiff-stemmed variety. Award of merit. These two were shewn by Mr. G. Carpenter.

C. Mona.—A good white single made up of several rows of substantial florets. Award of merit. Shewn by Messrs. Keith Luxford and Co.

C. Mrs. T. Hancock.—A large single with two or three rows of petals. It is of flattish shape and the basal primrose colour is heavily stippled with rich pink. Award of merit. Shewn by Messrs. Keith Luxford and Co.

PINKISH WHITE AND GREEN, BUDDLEIA AURICULATA.

MESSRS. BARRS AND SONS' INTERESTING COLLECTION OF VEGETABLES.

C. Raleigh.—A very good single of brilliant crimson colour with a golden centre. The ray florets are flat, regular and substantial. Award of merit. Shewn by Messrs. W. J. Godfrey and Son.

Nerine White Knight.—A large but loosely formed truss well furnished with flowers which have pleasant wavy margins. The pale pink segments have a median line of green. Award of merit. Shewn by Messrs. Barr and Sons.

Brasso-Cattleya Floss Flora.—An exceedingly beautiful flower of perfect proportions and large size. The sepals and petals are rosy mauve, the lip is crimson-purple with a yellow disc. Award of merit. Shewn by Mr. H. T. Pitt.

Cattleya Pittportia var. Lady Leon.—This is a hybrid variety, and is near *C. Portia* in general appearance. The plant bore large trusses of mauve flowers which have a purple lip. Award of merit. Shewn by Sir Herbert Leon.

Cypripedium Phantasy var. Sobriety.—A well formed flower of yellow colour tinged with purple.

The upper half of the dorsal sepal is white. Award of merit. Shewn by Mr. H. T. Pitt.

Lælio-Cattleya Profusion.—A finely formed bloom of soft rosy mauve colour with a broad ruby crimson lip and yellow disc. Award of merit. Shewn by Messrs. A. and J. McBean.

Odontoglossum Desdemona var. Rubens.—A quite distinct variety which bears a good spike of spotted flowers which have a broad rosy pink lip. Award of merit. Shewn by Messrs. A. and J. McBean.

Odontonia Philosopher.—A beautiful hybrid of *Odontoglossum* shape. The pale yellow ground colour is evenly spotted with claret and there are lines of the same shade of colour at the base of the lip. Award of merit. Shewn by Mr. H. T. Pitt.

Sophro-Lælio-Cattleya Pervanch.—This beautiful flower approximates the *Cattleya* in form. The broad sepals and petals are rose coloured flaked with gold, while the front of the lip is a deep crimson. Award of merit. Shewn by Mr. H. T. Pitt.

THE CHRYSANTHEMUM SHOW

The 11th. attended the annual show of the National Chrysanthemum Society at Vincent Square on November 1 and 2. It might have felt as though they had been transported to the land of the Arabian Nights, and that the magician had waved his wand for some purpose. Outside it was a dull and dreary world heavy and depressing with a moisture-laden atmosphere—within the hall floral brightness reigned supreme.

When dealing with the arrangement of competitive classes at a flower show it is no easy matter to make a homogenous and attractive display, but by the exercise of considerable taste, skill and fore-knowledge the management made a more than satisfying picture. Around the hall the chief trade growers had set up imposing groups of the finest Chrysanthemum the world knows. These were all different, yet, inasmuch as they were composed of lovely varieties of the same

flower, they were all in harmony. The most beautiful was the delightful display of Messrs. Keith Luxford and Co., and only a colour photograph finished by an artist could give any real impression of the wonderful colour values. Bright shades predominated, and while there were specimens of all shades of colour and all types of the flower, there were no harsh gradations, but each stand and bowl merged almost insensibly into the tones of its neighbours. The larger type of the market Japanese varieties included *Ruffinesque*, of formal habit and gold-tipped pink colouring, and *Sorcerer*, an orange bronze. Among the excellent Singles there were the small vividly coloured *Barbara*, *Phyllis Bryant*, *Mrs. Thos. Hancock* and *Mrs. W. J. Godfrey*; while the exhibition Japanese sorts included *Harry Clements*, *Rose Day*, *Poulton's Climax*, *Princess Mary*, *F. Spring Watts* and *Mrs. John Palmer*. In the front of this charming group, which deservedly

received a gold medal, there was a most entrancing display of the dainty little *Pompon* varieties.

While Messrs. Keith Luxford and Co. excelled in their arrangement, Mr. H. J. Jones was supreme with his imposing exhibit. Magnificent exhibition blooms were most prominent, and if only Mr. Jones could overcome the tendency to have a distinction between the "background" stands and the lower masses of bloom, his would be the ideal style of show group. But, as before with other flowers, he left something of a gap, with the result that the two styles did not combine to the greatest effect. Of the quality of such large Japanese sorts as *Rose Day*, *Majestic*, *Mrs. Gilbert Drabble*, *Mona Davis*, *Mrs. K. C. Pulling* and *Wm. Rigby*, as examples of the many, there could be no two opinions. Among the Singles he had such sterling novelties as *Mrs. A. B. Hudd*, *Miss Hazel* and *Jessie Robertson*. In this collection, which received the highest honour of a large gold medal and a Clay Gold Medal, there were also many good Japanese varieties of decorative size.

A gold medal was awarded to Messrs. W. Wells and Co. for a meritorious collection, which was composed largely of exhibition Japanese varieties associated with brilliant sprays of the *Scarlet Oak*, *Viscount Chinda*, *Mrs. George Monro*, *Mrs. Gilbert Drabble*, *Mrs. B. Carpenter* and *Wm. Rigby* are the names of only a few of the splendid sorts to be seen in this gold medal group. For general vase decoration they had delightful sprays of *Mabel Weston*, *Aphrodite*, *Phyllis Cooper* and *Blanche de Poitevine*.

A number of new and recent varieties of especial value for market cultivation were shewn by Messrs. Cragg, Harrison and Cragg. *J. H. Blythe*, a rosy shaded reddish crimson Single of brilliant apple orange; *Jessie Pattison*, which received an award; *Enid Elders*, of rich yellow colour; *Felix*, a rosy amaranth Japanese; and *Elspeth*, a spray flowerer of anemone type and satiny mauve shade, are all excellent.

Mr. Norman Davis had a restrained group in which *Norma Fairs*, *Mrs. Fred Fairs* and *In Memoriam* were prominent.

Sturdy plants, not more than 18 ins. high, of such Singles as *Exmouth Pink*, *Exmouth Sunset* and *Exmouth Glory* were shewn by Messrs. W. J. Godfrey and Son, who also had many cut blooms.

Other trade growers who set up valuable displays were Mr. Wm. Yandell, who shewed decorative sorts in a very attractive manner; Messrs. J. W. Cole and Son, who had a very pretty group containing such splendid Singles as *Absolute*, *Mrs. R. H. Harris* and *Mrs. T. Hancock*; Mr. H. Woolmer and Mr. L. Mills.

The competitive classes were generally filled with as good blooms as has ever before been seen at any previous show of the Society. The only weak spot seemed to be in the Incurved section, and these were distinctly poorer than the exhibits of last year. The greatest interest was centred in the classes for exhibition blooms shewn in vases. The first of these classes required thirty-six Japanese blooms in twelve varieties. Captain R. B. Brassey, *Cottesbrooke Hall*, Northampton, who won the first prize, was able to shew 108 perfect blooms. The vase of *Majestic* was particularly good, and this variety seemed to be the flower of the show, for it was to be seen in many exhibits and always of great merit. *Mrs. George Monro*, of rich velvety crimson colour, was another noteworthy sort. *Rosemary Simmonds* and *Princess Mary* also were wonderfully fine. The second prize was won by Mr. E. G. Mocatta of *Addlestone*, who had the best thirty-six exhibition blooms shewn on boards.

The other large class was for eighteen Japanese blooms in six varieties of stipulated colours, and here the *Dowager Lady Annaley*, *Holderby Hall*,

MESSRS. KEITH LUXFORD'S FINE EXHIBIT.

AN EXHIBIT BY MESSRS. J. W. COLE AND SON INCLUDED SOME SPECIALLY FINE SINGLES.

Northampton, won chief honours with a magnificent collection which included in a vase of Majestic the best blooms in the whole Show. Victory, Mrs. George Monro and Mrs. G. Gibson were also of great merit. The second prize was won by the Lord Wandsworth College, Long Sutton.

large Japanese varieties. The Exors. of the late Marquess of Ripon, Coombe Court, Kingston, were successful in the decorative classes, and also won first prizes with vases of small-flowered Singles, Anemone Singles and a vase of large Incurves.

THE FINE NEW EXHIBITION CHRYSANTHEMUM NORMAN DAVIS.

The best vase of three white Japanese blooms was of Mrs. Gilbert Drabble, shewn by Mrs. McDowell, Little Heath Wood, Potters Bar. Mrs. R. C. Pulling was a popular bloom in the similar class for a yellow variety, and the first prize was won with it by Captain C. O. Liddell, Shirenewton Hall, Chepstow. Splendid blooms of Edith Cavell set up by Mr. W. H. Allen were placed first in the class for a vase of any colour other than yellow.

The first prize vase of six Incurved blooms, shewn by Mr. L. E. Chalmers, Farrants, Bickley, was fairly good. The Incurved varieties shewn on boards failed to illustrate the decorative value of this type, and they were decidedly inferior to the exhibits of last year.

The large Japanese blooms shewn on boards were thronged by the usual crowd of admiring and criticising experts. Mr. E. G. Mocatta, Addlestone, won the Holmes' Memorial Challenge Cup with a magnificent collection of thirty-six distinct blooms. The chief varieties were A. F. Tofield, Wm. Rigby, Mrs. G. F. Sawyers, Majestic, Rycroft Triumph, Princess Mary and Peace.

Major Dalgety, Lockerley Hall, Romsey, had the best twenty-four blooms, and also was first with twelve and with six blooms. In each class he had a superb exhibit.

Single Chrysanthemums fully maintained their popularity with exhibitors and the public, and this decorative type was excellently shewn. The George Monro Challenge Cup was won by Mr. F. J. Yarrow, St. John's Wood, who had a delightful vase of Crimson Velvet, a variety which in this and other classes attracted a deal of admiration for its grace of form and charm of brilliant colouring. Mrs. W. Smith, Molly Godfrey and Reginald Godfrey were also especially good in this exhibit. Mr. Yarrow was also first with an imposing large vase of Single Chrysanthemums and another of

These "decorative classes," which aim at illustrating the value of Chrysanthemums in the house, were generally well contested, and the new class initiated by the President (Sir Jeremiah Colman, Bt.) was especially popular with the members, though few of them seemed to realise its full objects. According to the schedule it was for "an arrangement of Chrysanthemum blooms suitable for a hall, a hall table or sideboard decoration," thus allowing a wide margin of treatment. In one or two instances epergnes were used. Others contented themselves with one large ornamental jar and a couple of the ordinary flower show vases—a most incongruous association. The first prize was awarded to Mr. G. Richardson for an example of the last-named method. His jar of Majestic Chrysanthemums was very handsome. The second prize was awarded to Mrs. Robinson, Bourne End, for an overpowering display in which foliage too largely predominated. Mr. Richardson was also first with a well arranged bowl of Chrysanthemums.

The second prize basket of Chrysanthemums exhibited by the Exors. of the Marquess of Ripon was very charming. Mrs. Robinson was placed first with an immense affair which was chiefly basket and foliage.

The Affiliated Societies' Class was well contested, and the collections of the various types were especially attractive and educational. The Surbiton, Kingston, The Dittons and District Society (secretary, Mr. T. Smith) was first, the Eastbourne Society (secretary, Mr. J. Ticehurst) was second and the Berkhamstead Society (secretary, Mr. J. K. Bedford) was third.

NEW CHRYSANTHEMUMS.

Aldyth.—A medium-sized market Japanese variety with graceful drooping florets of rich

crimson colour. The golden reverse shews on occasional mature florets and on those in the centre. First-class certificate. Shewn by Messrs. Cragg, Harrison and Cragg.

Dorothea Edwards.—A compact exhibition Japanese variety made up of long, narrow, slightly twisted florets of bluish mauve colour. We do not think it will appeal to many growers. First-class certificate. Shewn by Mr. Norman Davis.

Flame.—A strikingly beautiful Single Chrysanthemum of rather more than medium size and perfect shape. The bright yellow ground colour is very heavily overlaid with crimson except around the disc. First-class certificate. Shewn by Mr. P. Ladds.

Felicia.—A market Japanese variety of flattish shape and only moderately furnished with broad petals which recurve at the tips. The clear pink colour is very beautiful, but we doubt whether the blooms would "carry well." First-class certificate. Shewn by Messrs. Cragg, Harrison and Cragg.

Gloriosa.—A large market Japanese variety of graceful habit which has broad florets of orange buff colour with a suggestion of old rose in the centre of the flower. First-class certificate. Shewn by Mr. H. Shoesmith.

Gigantic.—An exhibition incurving Japanese variety with variable pale bluish shading. Some of the flowers have lines of deeper colour on the florets. First-class certificate. Shewn by Mr. H. Shoesmith.

Jean Pattison.—A handsome market Japanese variety made up with stiff florets of fiery tangerine orange colour. First-class certificate. Shewn by Messrs. Cragg, Harrison and Cragg.

Mrs. W. E. Calow.—A splendid Single yellow Chrysanthemum of large size perfectly round and attractively reflexed at the tips. First-class certificate. Shewn by The Bridgewater Nurseries Company.

Mrs. W. Seymour.—An Incurving Japanese variety of exhibition size which has long, gracefully twisted florets of deep canary yellow colour. First-class certificate. Shewn by Mr. W. Barber.

Mrs. A. B. Hudd.—A good, large Single yellow Chrysanthemum of flattish round shape and recurved tips to the florets. First-class certificate. Shewn by Mr. G. Carpenter.

Norman Davis.—A brilliant exhibition Japanese variety much like Mrs. George Monro in size and colour, but has slightly twisted florets and is a rather brighter crimson. First-class certificate. Shewn by Mr. W. Jinks.

Progress.—A very moderate Incurved Chrysanthemum of mauve colour paler in the centre. First-class certificate. Shewn by Mr. H. W. Thorpe.

The Wizard.—A fine market Japanese variety of compact habit and dull orange cardinal colour. First-class certificate. Shewn by Messrs. Cragg, Harrison and Cragg.

FORTHCOMING EVENTS.

November 12.—United Horticultural Benefit and Provident Society's Meeting.

November 13.—Royal Horticultural Society's Fortnightly Meeting.

November 14.—East Anglian Horticultural Society's Meeting.—Aberystwyth Chrysanthemum Society's Exhibition.—Lewes Horticultural Society's Meeting.

November 15.—Aylesbury Chrysanthemum Society's Exhibition.

November 16.—Blackburn and District Horticultural Society's Exhibition (two days).—Dunfermline Horticultural Society's Chrysanthemum Exhibition (two days).

November 17.—Stockfield Chrysanthemum Society's Exhibition.

CORRESPONDENCE

GENTIANA FARRERI.

IN reply to "Albyn's" enquiry in *THE GARDEN* of October 20 as to the method of culture of *Gentiana Farreri* from seed, I sow the seed at the end of February in slight heat, and it germinates in about ten days. The seed is very fine and should be sown thinly, as every seed appears to germinate. The seedlings are pricked out into boxes and kept growing on under glass till the end of July, when they are planted out and flower the following autumn. I find seedlings vary very much in size of flower and shade of blue. Some of the seedlings flowering this year are much later in coming into flower and are of a darker blue than the ordinary *Gentiana Farreri*, and it is quite possible these late-flowering ones may be a cross by the bees between *G. Farreri* and *G. sino-ornata*. I have, this year, hand-fertilised some of the blooms of *G. Farreri* with pollen from *G. sino-ornata*, and got some seed from this cross which will be sown in the spring, and I am looking forward to seeing them flowering some day.—A. H.

A GLADIOLUS SOCIETY?

IN reply to your correspondent "Perplexed," a *Gladiolus* Society would certainly prevent a duplication of names, such as he describes, by issuing certificates of registration, each application to be accompanied by a few spikes of the variety the name of which it is desired to register for the Floral Committee to see. Should the proposed name have already been registered by another raiser, the second raiser would be informed and asked to select another name. In the case of Kelway's Marshal Foch, they would be informed that a *pink* variety already bore this name, and that in endeavouring to register a scarlet variety under that name they were likely to cause confusion. In requiring a few spikes with the application, the society would prevent applications being made for names for non-existent seedlings, and if the seedling were a good one, they could take the opportunity of setting their seal of approval on it by making an award of merit. In regard to duplication of names, the society would need to work in conjunction with the American and Dutch *Gladiolus* Societies. This is done by the American and British Carnation Societies now.—A. PAYNE, *Platlow, Essex*.

MANURES FOR RHODODENDRONS.

THE pert and practical remarks in the issue of *THE GARDEN* of October 20 by "Formakin" about animal manures for *Rhododendrons* can be verified by myself. Several years ago I was in charge of a garden in which a large number of named *Rhododendrons* had been planted two seasons previous to my engagement. The foliage and growth at the time I took over appeared sickly and very unhealthy. The following autumn I had 6ins. of the surface soil taken off, forked up the second spit, and applied 3ins. of well rotted dung and 3ins. of fibrous loam. The second year after this these *Rhododendrons* grew like Willows, and to say they revelled in their surroundings does not sufficiently express the difference in health. As regards their liking for crushed bones, I also know this to be correct, as the compost always contained bones when I was growing them in pots. I invariably obtained the best results from a mixture largely consisting of fibrous loam, which I found built up the flower-truss in better form than a peaty compost. This was especially noticeable with the variety *Pink Pearl*.—GEO. LOVELOCK.

AN UNPRUNED BOUGAINVILLEA.

YOU will remember that last year I sent you a photograph of *Bougainvillea glabra* growing in a small tub and never pruned (issue for July 29, 1922, page 374). To shew the advantage of this simple method of culture I enclose another picture of the same plant taken in the middle of October this year, shewing the beautiful effect being carried on right into the dark days, when it is especially welcome. This is largely due,

AN UNPRUNED BOUGAINVILLEA GLABRA IN MID-OCTOBER.

of course, to the retarding effect of the cold weather experienced in early summer.—H. C. W.

THE FIFTY BEST ALPINES.

MY list of fifty best alpine is culled from my notebooks, from observations made in my own gardens, and those of my friends. In a quantity so small as fifty many most beautiful alpine, of necessity, cannot be included. Some are old and perhaps considered out of date, however, they are some of my favourites.

Aster alpinus, *Ethionema grandiflora*, *Alyssum saxatile citrinum*, *Androsace lanuginosa*, *Anemone alpina*, *Aquilegia alpina*, *A. Stuartii*, *Arenaria balearica*, *Aubrietia Fire King*, *Campanulas Allioni*, *G. F. Wilson*, and *pusilla* Miss Willmott, *Cheiranthus linifolius*, *Dryas octopetala*, *Daphne Blagayana*, *Dianthus alpinus*, *D. grautensis*, *D. neglectus*, *Erigeron aurantiacus*, *Gypsophila monstrosa alba*, *Geranium argenteum*, *Geum montanum*, *Gentiana Farreri*, *Lithospermum prostratum Heavenly Blue*, *Hutchinsia alpina*, *Iberis Little Gem*, *Iris cristata*, *Linaria alpina*, *Mimulus Brilliant*, *Myosotis alpestris*, *Mazus rugosus*, *Onophalodes cappadocica*, *Nepeta Mussini*, *Oxalis eumephylla*, *Pentstemon heterophyllus*, *Phlox Vivid*, *P. Nelsoni*, *Primula Bulleyana*, *P. rosea*, *P. Lissadell Hybrid*, *P. Moerhousii Hybrids*, *Ranuncula pyrenaica*, *Ranunculus glacialis*, *Saxifraga Burseriana Gloria*, *S. longifolia* (out of flower, for foliage), *S. Cotyledon pyramidalis*, *S. trifurcata* (for quickly covering large spaces), *S. Wallacei*, *Sedum dasycyphium*, *S. lydium* (a lovely plant when well grown, but

difficult), *S. spectabile atropurpureum*, *Shortia galacifolia*, *Soldanella alpina*. I find I have given more than fifty, but still large quantities are left out. I find a note of an old *Potentilla formosa* that I prefer to all the modern introductions.—JAMES PARKINSON, *Harrington*.

Potentilla formosa is much grown in gardens to-day under its more correct name of *nepalensis*. *P. n. Willmottiae* is by most considered better than the type.—ED.]

ASSUMING the selection to be strictly kept to alpine plants and in a sense to be of a general usefulness for furnishing the rockery, I herewith

append a selection, well knowing them to be adaptable for the purpose.

Oxalis eumephylla, white; *Phlox subulata* G. F. Wilson, lavender; *P. Newry Seedling*, mauve; *Saxifraga Elizabethae*, yellow; *S. Haagii*, deep yellow; *S. splendens*, crimson; *S. Clibrani*, red; *S. Burseriana Gloria*, white; *Ranuncula pyrenaica*, lilac blue; *R. p. alba*, white; *Potentilla nitida*, bluish; *Onosma tauricum*, lemon yellow; *Lewisia Tweedyi*, orange pink; *Houstonia serpyllifolia*, pale blue; *Iberis saxatilis*, white; *Geum montanum* yellow; *Gentiana angulosa*, bright blue; *Erinus alpinus*, rosy purple; *Cypripedium Calceolus*, pale yellow and brown; *Dianthus alpinus*, rose; *D. neglectus*, pink; *Aster alpinus*, violet; *Aubrietia Crimson King*; *A. Pritchard's Art*, violet; *Campanula Rauteri*, dark blue; *C. W. H. Paine*, violet and white; *Androsace lanuginosa*, pink; *A. sarmentosa*, pink; *Achillea Kellereri*, white; *Primula viscosa*, rosy purple; *Shortia galacifolia*, pink fringed; *Sedum reflexum cristatum*; *S. primuloides*, pink; *Soldanella alpina*, blue; *Viola gracilis lutea*, yellow; *V. gracilis*, purple; *Wahlenbergia albo-marginata*, white, tinged blue; *W. saxicolor*, light blue; *Thymus micans nanus*; *Sedum kamschaticum fol. var.*, orange; *Saxifraga sanguinea superba*, bright red; *Saponaria oermondes splendissima*, pink; *Morisia hypogaea*, gold; *Onophalodes verna*, blue; *Lithospermum Heavenly Blue*; *Scabiosa silendifolia*, blue; *Silene Saxifraga*, white and pink; *Primula Julia*, rosy purple; *Lewisia Cotyledon*, crimson and golden yellow; *Oenothera eximia*, white.—G. L.

FROZEN FLOWERS IN TRAFALGAR SQUARE.

AMONG the many flowers and decorations round the Nelson Column on Trafalgar Day I looked with great interest at two solid blocks of ice containing wreaths of fresh flowers sent from New Zealand and South Africa. The wreath from the latter country appeared to be composed entirely of orange-coloured Gerberas. (I think this was the flower, but write—in the absence of books of reference from recollections of Riviera gardens.) The New Zealand wreath appeared to be a mixture of small flowers with ferns and moss—the ice in which they were still completely enclosed was rather clouded and melting fast, and the rope barriers kept one too far away for a close inspection. I could only make out a little mauve colour and what looked like transparent green berries. The view one got was rather tantalising to a flower-lover. I believe the importation of flowers in ice is not unusual now, though I have never before happened to see any of these frozen flowers. The captain of the SS. Naldéra, in February, 1922, when I made the voyage from Marseilles to Tilbury, told me he had on board a bouquet of flowers in ice brought from Australia for Princess Mary's wedding, but it was in the cold storage room and not visible. I wonder if it is ever possible to see these flowers from distant lands at close quarters and at leisure? The smaller wild flowers which are not grown in our gardens and greenhouses would be particularly interesting. I imagine when once the ice is melted the flowers must have a very short life indeed, but I suppose when quite close by, they can be very clearly seen through the ice.—RUTH BICKERSTETH.

DOUBLE PRIMROSES.

I SUPPOSE your correspondent "N. H. P." is right in speaking of the Double Lilac Primrose (lilacina) as being "seldom seen nowadays"; though, was it at any time at all common? I am prompted to this question by the recollection that, when shewing this plant at Vincent Square this and other years, so many people who see it imagine it to be a new plant, and are much surprised when I tell them I knew it well as a child. So few seem to know it, but, seeing it, most people express their admiration for it. It is, indeed a beautiful plant and, as your correspondent says, a vigorous grower; it flowers over a comparatively long period, and well grown plants produce a large number of blooms. An exceptionally fine group that I had the pleasure of exhibiting at the Royal Horticultural Society's Hall this spring attracted the notice of Her Majesty Queen Mary, who graciously made enquiries about it. At that same meeting also I had one or two plants of Pompadour, the "beautiful old Pompadour" as your correspondent aptly describes it. That certainly is a rare plant, but of a small number that I had growing in the nursery this spring one plant was conspicuous for its fine strong and healthy growth, numerous large and richly coloured deep crimson velvety flowers and general appearance of well-being. I had only recently acquired these plants, but seeing that one, at any rate, seemed so conspicuously well suited here, I am hoping that we may in time raise a good stock of the glorious old beauty, of which it would scarcely be possible to say too much in praise. Perhaps equally beautiful, though not finding so many admirers as Pompadour or lilacina, are the two other old varieties, the Double White and the Double Sulphur. These thrive here quite as vigorously as lilacina. The white variety had a number of blossoms a week or two ago, and I see that at present the sulphur is in flower.—FREDERICK G. WOOD, *Ashted*.

I READ with interest "N. H. P.'s" note on double Primroses in your issue of October 27, and I am glad to be able to tell him that there are still a few plants of the double crimson Primrose Pompadour in existence. I had some sent to me by an Irish firm last autumn to try in our climate in North Wales, and I am very pleased with the result. They are growing well and commenced to bloom the beginning of this month in the open ground. I may say that the charming little double crimson Auricula Cardinal also does very well in the open here.—W. A. WATTS, *The Welsh Bulb Fields*.

KNIPHOFIA COMOSA.

IN "W. L.'s" interesting article on the Torch Lilies (October 6, page 509) he states that the flowers of Kniphofia comosa and K. Leichtlinii open from the top of the spike downwards. This procedure is exactly opposite to what happens in other species and varieties. "W. L." also refers to the branching habit of K. comosa, in that many of the primary spikes produce secondary spikes.

At Kew and at the John Innes Horticultural Institution this species flowered freely this year

KNIPHOFIA COMOSA, SHEWING CURIOUS METHOD OF FLOWERING.

and produced many branched inflorescences. The flowers on the secondary spikes open the opposite way, i.e., from the base upwards, thus shewing a reverse order of opening of flowers on the two spikes. This is a very interesting phenomenon and worthy of being placed on record. It would be interesting to observe whether any other species has this branching habit and, if so, to notice how the flowers open on the primary and secondary spikes.—A. HOSKING.

A SLUG TRAP.

I HAVE just read "Slugs Rampant" in THE GARDEN for October 27. I wonder if "T. A. L." has ever tried orange skins as slug traps. I have never found anything to equal them. Take an orange, cut it in half and scoop out most of the fruit. Put the skins down where slugs abound, under the shade of a plant is best, and if the soil is smooth, tilt them slightly so that the slug can crawl under easily. I have often caught twenty to thirty in one night in each orange skin by this method. There is no need for the tiresome nightly search with a lantern, provided the skins are taken up and cleared in the morning before the sun gets on to them, as slugs will remain as long as there is any juice left in the orange, unless driven away by heat. I cleared a large strawberry

bed entirely of a veritable plague of slugs this way, and I once took 1,500 in two days. Oranges are easy to get, and the fruit scooped out need not be wasted. I once told a doctor about this and I heard a rumour afterwards that his patients were doing an "Orange cure" and his garden was "slugless," which was very satisfactory, and think how pleasant for the patients too!—F. F. S. W.

HOLLAND PARK SHOW.

A QUESTION that has been raised, I am told, and seems likely to bear fruit, is—whether it would not be greatly to the advantage of all concerned to hold a separate Autumn Show for competitive classes of fruit and vegetables in the R.H.S. Hall at Vincent Square and leave Holland Park entirely to flowers and shrubs and perhaps groups of fruit and vegetables. It seems a pity that such fine exhibits of fruit and vegetables as were put up at the Show this autumn should be mostly relegated to the balcony for want of space. It is quite certain that great numbers of the public do not seek them in their exalted position and so miss some most interesting exhibits. Apart from this, it does not give the exhibitors

themselves a fair chance to shew their products off to advantage. The Royal Horticultural Society never fails to look for and carry out any possible improvement in its shows, so I feel confident that we shall see the desired alteration in this direction next year.—ENTHUSIAST.

THE CLIMBING CAPABILITIES OF A HYBRID TEA ROSE.

ABOUT five years ago we decided to devote the space on the back wall of a peach-house—then occupied by a worn-out Peach tree—to growing Roses, and as we had a couple of strong plants of Mme. A. Chateau which had been grown in pots for about the space of six years, these were selected for the purpose. They have done extremely well in the soil of the peach border, and now cover the wall to its full height of 10ft. and, being grown with a minimum amount of fire-heat, give very fine blooms. Last spring we had them with 20in. to 30in. stems. Particulars as to the growth made by the plants under notice being mentioned to an expert in the rose-growing world at that time, he declared they must be the climbing form of Chateau, and when it was pointed out to him that we had had the plants for years before the climbing form was introduced (Messrs. B. R. Cant and Sons' catalogue states the date as 1917 by W. Easlea), he said we must have got this form before Easlea's introduction, which is described as "producing growth of 7ft. to 8ft. in one season." I have never known our plants to make more than 5ft. shoots without breaking off into a bunch of flower-buds, which is not the habit of a true climbing Rose. By allowing a length of 2ft. to 3ft. when pruning it is possible to cover a wall like the above in the course of a few seasons, and I feel sure that any of the vigorous varieties of the Hybrid Tea class would do the same under similar conditions.—R. DEAN, *Andleys Wood Gardens, Basingstoke*

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Asparagus.—Facilities are often meagre for forcing vegetables, but it one can supplement the usual supply by an occasional dish of something not in season, they are always greatly appreciated and credit is due to those who undertake the task. Asparagus is a delicious vegetable, which can be forced at any time during the winter months. A deep brick pit with hot-water pipes is suitable, the latter only being employed when necessary. The pit should be filled with leaves and long fresh manure, and covered with soil to the depth of about 6 ins. When the rank heat has escaped the roots should be placed closely together and covered with 3 ins. of fine soil. In some establishments plants are grown especially for forcing, but it often happens that new beds are formed, and when these begin to yield the old plantations are discarded. If the roots are lifted carefully, a large number will be found suitable for forcing. Do not expose the roots for any length of time, and when they are placed in the pit keep the soil just moist, while the temperature should be about 55°. Very little ventilation is needed, and the lights may be covered with mats at night to keep up the temperature.

General Work. During wet weather the store shed should be given attention, and Potatoes, Onions, etc., examined, all diseased specimens being removed and burnt. Crops that have finished may be cleared, and all decaying vegetable matter collected and buried in a trench. Manure can be put on vacant plots, choosing if possible a frosty morning for the work, and both ordinary digging and trenching ought to be done with all possible speed. This will relieve the rush of work in the spring, and if the soil is laid up in a rough condition both frosts and air will mellow it, and when seed time arrives it will only require to be made level with a wooden rake. It is always advisable at this season to examine notes taken on the various crops during the past year. Some varieties will be discarded, while others have succeeded remarkably well. Mistakes can be recorded for future guidance.

The Flower Garden.

Border Chrysanthemums are almost indispensable for the border and cutting purposes during the autumn months, and they are worthy of wider cultivation, especially now that there are so many admirable varieties in commerce. Here, they remain in the borders throughout the winter, but in most places it is advisable to lift a number of plants for stock purposes. A label should be securely attached to each plant, then the roots may be lifted, placed closely together in boxes and stored in a frame or cool greenhouse. Admit plenty of air, when the weather is favourable, to promote sturdy growths, which will furnish cuttings later on.

Leaves.—Leaf-mould is always acceptable in gardens, so at this period the leaves should be collected and stored in a suitable spot where they can remain for at least a year. It is a bad policy, however, to remove them from shrubberies; it is better to wait till they have all fallen, and then cover them with soil.

Lawn Mowers.—Before putting them away for the winter all parts of the machines should be thoroughly cleansed and given a coating of oil. The order can be given for any new parts, and the knives ground and set at the first opportunity in readiness for another year.

Climbing Plants.—Where these are trained on poles or buildings it will be necessary to thin the growths and cut some of them back to keep the plants within their allotted space. New poles will be needed in some instances, but, where possible, such strong-growing plants as Vines, Clematis montana, etc., should be planted at the base of old trees and allowed to ramble without any interference.

The Hardy Fruit Garden.

Pruning. The pruning of fruit trees should be proceeded with, but where birds are numerous it is advisable to leave Gooseberries and Currants till a later date unless they can be protected. Orchard standard trees will need attention, and as a rule a certain amount of thinning of the shoots to prevent overcrowding will be necessary. All growths crossing each other should be removed, and any of the outer shoots, perchance, cut back to produce a shapely specimen. The chief fault with orchard trees is overcrowding, and in some instances it may be expedient to cut out a few

of the larger branches to allow both light and air to enter the trees.

L. W. BEISCOL.

(Gardener to W. R. Lysaght, Esq.,
Castleford, Cheltenham, Gloucestershire.)

FOR NORTHERN GARDENS.

The Kitchen Garden.

Pea Trenches. Peas rank so high among vegetable supplies that no pains should be spared to ensure full crops of the best quality. As a rule, first and second earlies should be sown on the flat, but mid-season and late varieties should be sown in specially prepared trenches; indeed, on soils of a light nature this mode of culture is essential to success. The best time to prepare the trenches is at this season, when the winter digging of the quarter is being carried through. A good rotation is to follow Celery with the Pea crop, and when this is done, and the Peas are sown in the Celery trenches, little extra preparation is necessary except to finish the trench about 6 ins. below the ground level. New trenches should be taken out from 2 ins. to 2½ ins. deep, and a layer of farmyard manure be placed in the bottom. They should then be filled up to within 6 ins. of the ground-level with part of the excavated soil, plus whatever organic manure may be available. A proportion of decayed vegetable manure will prove highly beneficial. The object in view in adopting the trench system is, chiefly, to obtain cool conditions for the roots during the heat of summer and to admit of the crop being more thoroughly watered if drought occurs. If the Pea crop is to be confined to a limited area, the distance between the lines should correspond with the height of the variety being dealt with, but the better plan is to arrange the lines rather widely apart, utilising the intervening spaces for the culture of dwarfier plants.

Saladings.—Mustard and Cress grown in moderate heat, and renewed every ten days or so, will, in addition to Celery, be the only source of supply in the North during the winter months. Keep an eye on autumn-sown Lettuces for early supply next spring, and, if slugs appear, give the plants an occasional light dressing with soot.

The Hardy Fruit Garden.

Late Propagation.—Late cuttings of Gooseberries and Currants may still be inserted with every chance of their rooting. With the exception of Black Currants, the cuttings, when prepared, should be about 1½ ins. in length, and have all the buds removed except three or four at the top. This admits of the cuttings being inserted in the soil to a depth of from 5 ins. to 6 ins. and gives several inches of clear stem above ground. Cuttings of Black Currants need not be more than from 6 ins. to 8 ins. in length, as a clear stem is not necessary with them owing to the mode of pruning best suited for them. When inserting the cuttings stretch the garden line tight and take out a trench 6 ins. deep with the spade. Then set the cuttings in position 6 ins. apart against the line, partially filling in the soil as the work proceeds. When a line is filled with cuttings, fill in the remainder of the soil and tread it firm. The lines of cuttings should be 1 ft. apart.

Pruning Currants.—Carry through this work when the ground is in a fairly dry condition. Red and White Currants should be pruned on the spur system, but the framework of the bushes should be kept intact with healthy wood. Black Currants should be kept up with successions of young wood, spurring not being advisable with them. A look-out should be kept for big-bud.

Wall Trees should be gone over after being pruned: first, to renew any shreds or ties that have become decayed; next, to unfasten and renew any that have become too tight, and, thirdly, to train any young or extension shoots. Although comparatively expensive, medicated shreds are much to be preferred to the ordinary woollen shreds as being more lasting and as less likely to harbour pests.

The Flower Garden.

Climbers.—Certain climbers should now receive attention. Buddleias should be pruned by cutting back the breastwood to two or three eyes from its base; Clemathuses should have any extra vigorous shoots cut back; Virginian Creepers should be clipped hard in. Clematises of the Jackmanni type, i.e., those which flower on the current year's wood, should be cut back to within about a yard from the ground, while those which flower on the old wood should have the shoots thinned out a little; care being taken to see

that they are well secured to wall or trellis, as the case may be.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Humea elegans.—Plants raised from seeds sown during July and August should now be ready for putting into 48-sized pots, in which they will stand until early in the New Year. Humeas require careful watering at all times and perfectly cool conditions, as a close, stuffy atmosphere soon spoils them.

Lindenbergia grandiflora.—This plant is now flowering, and it is very useful for the cool greenhouse, as it lasts in blossom for a long time. As the species is nearly hardy, it is well worth growing for the small unheated greenhouse, its pale yellow flowers being very attractive. It is easily propagated by means of cuttings during the spring, and it may also be increased by means of root cuttings.

Camellias that have set a heavy crop of buds will now require to be disbudded. If this is not done the chances are that most of the buds will drop off. Allowing the plants to carry too heavy a crop and dryness at the root are generally the causes of bud dropping. Although care should be taken that they do not get dry at the root, overwatering during the winter is equally bad. The leaves of Camellias sometimes get covered with a black sooty deposit; when this happens they should be sponged. They are also apt to suffer from attacks by scale insects, and these should be eradicated by sponging with soft soap and water or some approved insecticide. If the plants are healthy, a vigorous use of the syringe during the summer months will do much towards keeping them clean. With the introduction of many beautiful single varieties Camellias are again becoming popular. Some good single varieties are CC. japonica grandiflora Kimberley, White Swan, Lady Clare and magnoliaeflora. Lady Ardilaun is a small white-flowered variety with an anemone centre to the flower. Unlike most Camellias, the flowers of this remain on the plant for quite a long time before they fall off. The flowers of C. roseaflora behave in the same way. This variety has very small double rose-coloured flowers and very slender shoots, with small leaves, and is a very charming plant. Some varieties of Camellias may be readily rooted by means of cuttings. They are useful as stocks for grafting the varieties that do not root readily. Cuttings may be put in at this time, selecting the more slender and twiggy shoots for this purpose. They are best placed in a case in a cool house until they have callused; then, if they are given slight bottom-heat, they usually root readily. Grafting may also be done at this time, side grafting being the easiest and most successful method. Camellia reticulata is the finest of all the Camellias, and is seen at its best when planted out in a cool conservatory in a compost of medium loam and rough fibrous peat. Stock of this plant is always scarce; this is, perhaps, because its propagation is imperfectly understood. It is grafted on stocks of Camellia japonica, but side grafting is the only successful method, and in selecting the scions a portion of two year old wood must be secured, scions of the current year's wood usually giving many failures.

Luculia gratissima is now showing its flower-buds, and as they are subject to attacks by mealy bug, care should be taken to keep them free from this pest. At this stage the bugs are best removed by means of a soft brush, taking care not to damage the flower-buds. This plant has always—and not without reason—been regarded as difficult to propagate. That it can be successfully rooted and grown on in the same way as Hydrangeas is proved by the fact that a number of plants rooted during the spring have made growth about 15 ins. long, and in every case flower-buds are now showing. They have been grown throughout in a warm close house with a temperature of 60° to 65°, and have retained their foliage. This is interesting, as this plant usually does not do well under pot culture, and when grown in a cool house, as a rule, loses most of its leaves. Of course, when planted out, it grows perfectly well in a cool greenhouse.

Pernettya mucronata.—Small well fruited plants of this hardy evergreen shrub are very useful for furnishing the cool greenhouse during the winter months. They may be lifted from the open ground at this time and placed in suitable-sized pots. When they have done duty in the greenhouse they should be planted out in the nursery garden and grown on for future use.

Gardeners' Provident Society. The annual dinner of the United Horticultural Benefit and Provident Society was held on November 1 at the Imperial Hotel, Russell Square, London, Sir W. Lawrence, Bt., presided, and was followed by Lady Lawrence. Sir William made a short speech. It was pointed out that the members of the Society were to provide assistance to gardeners in sickness and old age, and that upon the death of a member a sum of money would be paid to the deceased's relatives. The Society caters for those engaged in the nursery and seed trades, for florists and market gardeners, as well as for those employed in private gardens. The chairman promised to induce as many friends and acquaintances as possible to use their influence to persuade their employees to join.

Mr. Chas. Curtis, who has been chairman of the committee for a great many years, gave statistics shewing the good work the Society had achieved to date.

This is the only society of its kind and, if not for their sakes, for the sakes of their dependents, present or prospective, all working gardeners should join. Full particulars may be obtained from the Secretary, Mr. A. C. Hill, 35, Alexandra Road, West Kensington Park, W.14.

A Floral Fete for Southport.—The proposal to hold a big floral fête and water carnival in Southport next summer was very favourably received by the Parks and Foreshore and the Advertising and Band Committees of the Southport Corporation at their meetings recently. Both Committees appointed a Sub-Committee to co-operate in carrying out the necessary arrangements. This special Committee consists of Aldermen Aveling and Wood, Councillors Clayton, Wilkinson, Brook, Rhodes, Potts, Lean and G. R. Crankshaw. We are informed that it is intended next year to hold a fête at Southport which is to be on the lines of the famous Shrewsbury Flower Show, and that it will be held during the week following that event. Although the dates have not been definitely fixed, these will probably be Wednesday, Thursday and Friday, August 27, 28 and 29. The exhibits are to be housed in a huge marquee covering about an acre of ground in the Victoria Park, alongside which runs Southport's famous flower border, a most appropriate setting for a floral fête. It is proposed to offer prizes to the value of about £1,500, including nine silver challenge trophies, four or five of which will be of the value of £50 each and the remainder of the value of £25 each. Three of the trophies have already been offered. Although the schedule of the show has not yet been definitely decided upon, the challenge trophies will probably be allotted to suitable classes for rock or water gardens, fine foliage plants, Carnations, dishes of fruit, herbaceous flowers, Roses, Sweet Peas, Dahlias and early Chrysanthemums. The Horticultural Society of the London Midland and Scottish Railway (Northern Division), who last August held a successful flower show in the Victoria Park, Southport, will be invited to hold their 1924 show in conjunction with the Southport Floral Fête. The enthusiastic support of several leading firms and other gentlemen closely connected with the horticultural trade has already been secured for the Southport event. Music will no doubt be provided by one or more of H.M. Guards' bands. Horse leaping may also be included. The proposals include the holding in the evenings of a water carnival on the Marine Lake adjoining the Marine Parks, concluding with magnificent displays of fireworks. The inauguration of a 1924 annual floral fête during the Mayoralty of Mr. Alderman Aveling (who for the past three years has been the chairman of the Parks and Foreshore Committee) will be

peculiarly fitting and should certainly do much to enhance Southport's reputation for magnificent floral displays.

A Pretty Dwarf Carpeter. For covering cool, shady or half-shady ledges in the rock garden, about steps and the margins of paths that little New Zealander, *Nortera depressa*, is very delightful. It makes a dense but shallow carpet of vivid, glossy green, reminding one of *Helxine Solierohii*. *N. depressa* is not quite hardy, but it will often survive quite severe winters with a light covering of dry bracken, and it is not fastidious as to soil, provided the latter is not too stiff and heavy. The flowers of this dainty creeping plant are green and inconspicuous, but they are followed by small round fruits of a glowing orange-red which are distinctly attractive. *N. depressa* makes a good carpeting for any dwarf bulbous plants, and it is by no means difficult to propagate by detaching rooted bits and starting them in gentle heat. In districts which are exceptionally raw and bleak a few of such roots may be wintered in pots in a cold frame.

Trollius pumilus.—This is a Globe Flower which is unique in bearing golden yellow flowers which open flat like a saucer, a distinction which suggests that the common English name for the genus is not always a happy one. *T. pumilus* is a species that is of easy culture in any cool, moist, vegetable soil where it is not too shady. Since it only grows to some 6 ins. to 8 ins. in height, care must be taken lest it be overshadowed by others of the genus or any taller plants associated with it. The foliage of *T. pumilus* also differs from that of the Globe Flowers in general, the leaves consisting of broad, dark green, overlapping lobes of leathery texture. There is a form of this species known as *T. p. yunnanensis* which, though considerably taller and more leafy, is not more

attractive in blossom than the type. It is equally reliable under similar conditions and well worth a place.

A Compact-Growing Bugle.—There is an attractiveness about the Bugles which, however, ultimately leads to their own undoing, for most of the varieties of *A. reptans* are such rampant spreaders that few can tolerate their presence for long. But this cannot be said of *A. genevensis*, which, since it does not creep, is a species that can be trusted in the choicest company. Though a very old garden plant, hailing from Switzerland centuries ago, this is still comparatively uncommon, but its fine erect spikes of deep blue, 6 ins. to 8 ins. in height, are distinctly handsome and deserves to be better known. There is a variety called *A. g. Brockbankii* of which the flowers excel even those of the type in the richness of their colour. *A. genevensis* and the variety mentioned bloom in May and June. They prosper in any ordinary border soil, preferably in partial shade.

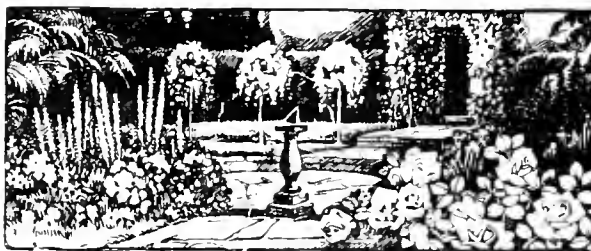

Answers to Correspondents

FLOWER GARDEN.

IRIS SEEDS (C. E. Y., Solihull).—The seeds should be nicely dried and stored in a paper packet in a cool, dry place through the winter if they are to be sown in spring. However, if our correspondent possesses a frame a portion of the seeds may be sown now and the remainder next March. A nice loamy soil passed through a tin mesh sieve will be suitable. Drain the pot well, water the soil before sowing the seeds, but do not water the covering soil for several weeks.

NEW SPRAYING MACHINES LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete without a Sprayer, in fact a Sprayer is absolutely essential to obtain best results. During the War we supplied a considerable number of our well known Four Oaks Knapsack Sprayers—Rubber Diaphragm type—to the Government, and we have just re-purchased a small quantity back again, which have never been used. They are

made of copper but painted Service grey colour. They have various special additions to the ordinary machines, and the price to-day would be £5 each. We guarantee them to be in perfect working order as new. We will send one machine carefully packed, carriage paid, on receipt of 50/-, but cash must accompany all orders. We would supply 2 machines for 90/-, carriage paid.

Please mention this Paper when ordering.

The World is made of—

ONE big reason why Kit is indispensable to gardeners is that the world is made of dirt. Kit, the rapid action hand-soap, can dig out of the pores of the hand any dirt that can get ground into them. Ordinary dirt it laughs at; paint and tar it can shift with ease; oil and grease it can banish at the first rub.

You'll notice that Kit leaves the hands feeling clean, as well as looking clean; that's because Kit has worked deeper than ordinary soaps can.

6d PER TIN.

HARDY BORDER AND ROCK PLANTS, TREES, including Fruit Trees, Ornamental Trees, Flowering Shrubs and Evergreens.

PENNELL & SONS - LINCOLN.

Nurseries established 1780.

The Rose the most beautiful flower

in all the world, with the delicate softness and symmetry of its petals, its gorgeous hues and tones creates an atmosphere of delightful rest and seclusion in any garden.

The King's Acre Nurseries famous since 1785 for the stamina and vigour of its roses—have hardy and reliable

STANDARDS, BUSHES and RAMBLERS

in a wonderful, almost endless, variety, which they are offering at prices considered by experts and amateurs to be beyond competition.

THE
King's Acre Nurseries Ltd.,
Established 1785. HEREFORD.

Notes from Maidstone.

GRAPE VINES & FIGS

The best Grapes are described in our list, which is sent free. We will not attempt descriptions in this limited space.

For Heated Houses we have all the best varieties — Muscat of Alexandria, Madresfield Court, Alicante, etc., etc., while for cold houses we recommend Black Hamburg, Buckland Sweetwater, Foster's Seedling, etc. Planting canes 15 -, 21 - and 25 - ; Fruiting canes 30 - and 35 - each.

FIGS. — All the best varieties for indoor or outdoor planting. Bush or Fan-trained 10 6 to 21 - each.

ROSES FOR BEDDING

IN his delightful "Book About Roses" Reynolds Hole writes: "To have both a beautiful rose garden and a garden of beautiful Roses requires the ground and the gold which few can spare." No doubt in those days this was true, but it can hardly be said to be so now. Dean Hole gives lists of Roses suitable for hedges, for pillars, for walls, for gardens and, what appeals to him most, "for exhibition"; but there is no list of Roses for bedding. Yet in modern books about Roses no chapter is more important than that which treats of varieties suitable for bedding. No question is more often put to us by our gardening acquaintances than this: "Which do you think are the best Roses for bedding?"

The twentieth century, though it may have brought us many troubles, has this to its credit, it has seen the birth of numberless beautiful Roses which have enabled us to plant our gardens in such a way that it is now possible even on a comparatively small piece of ground to combine a beautiful rose garden with a garden of beautiful Roses. The difficulty now in planting a moderate-sized rose garden is to decide which varieties will be most effective for our purpose.

A bedding Rose needs many good qualities, for it is asked to take the place of such old-fashioned bedding plants as "Geraniums," Begonias, or Calceolarias. Therefore it must be free and continuous in blooming, the colour and form of the flowers must be pleasing, the foliage good and abundant, the habit of growth upright, with the flowers borne on firm and sufficiently substantial stems, and they should have the added charm of fragrance. Personally, also, I prefer a variety which does not require constant attention in disbudding, and it is of great importance that the petals of the flowers should be sufficiently substantial to resist rain. Those Roses of which the blossoms, however lovely, turn

into brown balls if subjected to a few showers, are by no means first-rate for bedding. The ideal Rose possessing all good qualities in perfection has yet to be raised. Ophelia and Mme. Butterfly leave little to be desired as regards form, freedom and fragrance, but their foliage is somewhat scanty and their colouring not sufficiently brilliant to be effective at a distance. On the other hand, Mrs. Wemyss Quin and Mme. E. Herriot make vivid patches of colour in the rose garden and their flowers are set off with shining foliage, but they have neither the beauty

of form nor the delicious fragrance of the two first-mentioned varieties. Therefore in deciding what Roses to plant in our beds we must make up our minds whether we chiefly desire a very brilliant distant effect or whether we shall be content with beauty as shewn to us on closer inspection.

I take for granted that in our rose garden we grow our plants in beds of one variety or in groups if in borders. Were I to choose for those who ask first for brilliancy of colour and freedom of bloom, I should recommend the following:—

Crimson.

MRS. EDWARD POWELL is the best red Rose for bedding. It has a splendid upright habit, magnificent dark foliage, very bright red blossoms, freely and continuously produced; moreover, it is very hardy. The flowers, though large and with good petals, are not perfectly shaped, and though they are fragrant, they have not the true "old rose scent."

RED LETTER DAY and K. OF K. both make a fine display of brilliant almost scarlet flowers which are produced freely. They are nearly single and have practically no scent. If I could only grow one of these, I should choose K. of K.

ECARLATE is almost like a China in its freedom of bloom. It has a neat, rather dwarf habit and its flowers, though poor in form, are of a very pretty light crimson colour. They have little scent.

Shades of Pink and Salmon.

MRS. E. G. HILL is a very lovely bedding Rose with sprays of bright rose pink flowers, the reverse of the petals being a deeper shade. This Rose stands rain well and is sweet scented.

MRS. HENRY BOWLES.—This Rose, brought out in 1921, promises to make an excellent bedding variety with large well shaped blooms of warm pink, which are freely and fairly continuously produced.

MME. LEON PAIN, one of the freest of all Roses, is of stout

THE BEAUTIFUL NEW WARM PINK BEDDING ROSE,
MRS. HENRY BOWLES

A BED OF ROSE MRS. HENRY MORSE CARPETED WITH VIOLAS.

ONE OF THE BEST RICH YELLOW BEDDERS, GOLDEN EMBLEM.

THAT UNIVERSAL FAVOURITE, GENERAL MCARTHUR.

4. *Antioch*, but the foliage, and the shape of the flowers of salmon flesh. It is very pretty in the bud, but the full flower is rather heavy, and is easily spoilt by wet weather.

Yellow, Apricot and Orange.

MRS. WEMYSS QUINN must have pride of place as the most effective yellow bedding Rose. Its dark green glossy foliage is mildew-proof, and its brilliant yellow flowers are freely and continuously produced and are well carried on strong, straight stems.

GOLDEN EMBLEM has larger, better shaped and even more brilliant flowers, but they are not so numerous and the plant is not quite so hardy as Mrs. Wemyss Quinn. It has magnificent foliage.

LOS ANGELES, one of the best Roses of recent introduction, has large well shaped flowers of glowing apricot and orange. It is a fairly tall grower, an excellent autumn bloomer, and is fragrant.

EMMA WRIGHT has come to the front this year. Its flowers of almost pure orange are scented and freely and continuously produced, and they are set off by fine glossy foliage. The variety Severine is very similar, but of the two I prefer Emma Wright.

Coral, Flame Colour and Terra-Cotta.

THE WELL KNOWN MME. EDOUARD HERRIGT is certainly the most free-flowering and generally effective variety of this colour, its only faults being that it sometimes hangs its head, that the flower-stems are prone to mildew, and that its tints, though supremely brilliant, are apt to be rather hard and crude.

HENRIETTA is, to me, a far more pleasing variety. Its flowers of coral salmon tints are borne on smooth stems; they are very fragrant and in the bud stage are most brilliant and effective, but this is not nearly so free a variety as Mme. Edouard Herriot.

I will now describe those varieties which we should choose if looking specially for beauty of form combined with good habit and freedom of bloom. All the *white or creamy white varieties* I should recommend for bedding are well shaped Roses.

MRS. HERBERT STEVENS (F.) is wonderfully free-flowering, indeed, even as a bedding variety it needs constant disbudding. When attended to in this respect, its flowers are large, and they are nearly always good in form and stand rain better than any other white Rose I know; the foliage is rather skippy.

MOLLY SHARMAN CRAWFORD, also a Tea, has pretty dark foliage and stems which set off the full white blossoms; they have a tint of can de nil.

MME. JULIE BOUCHE (H.T.) is a good grower and produces freely well shaped flowers of white tinged with blush or salmon. This Rose is rather easily injured by rain.

To return to the Crimson Roses.

RICHMOND is a delightful bedder. It freely disbudded the flowers are of excellent shape and they are sweet scented.

CONVENT GARDEN is a Rose of splendid habit and ample foliage with well formed dark crimson blossoms. They lack fragrance and are not so freely produced as those of Richmond or Mrs. Edward Powell. It is a good autumnal flowerer.

HORTICULTUS BRILLI, a new variety brought out in 1919 by a Dutch firm (H. A. Vershuren and Sons), gives promise of being a fine addition to our crimson bedding Roses. It is glowing dark red, has good foliage and delicious fragrance, and I believe it is a really free-flowering variety.

I need not again describe the charms of Ophelia and Mme. Butterfly except to add that besides their wonderful beauty of form and purity of colour they are exceptionally free-flowering.

Writing on November 4, I can truly say that all through this wet October I have been able daily to cut first-rate blooms of both these varieties and the plants are still covered with buds.

There are many other varieties good for bedding; some, such as Caroline Testout, Lady Pirrie and General McArthur, too well known to need description; others, for example, Betty Uprichard, Independence Day and Mable Morse, almost too recently introduced to be recommended without

further knowledge, although, judging by the growth of two or three plants in our garden, I should certainly be tempted to try them.

I would always keep a bed for the old favourite Mme. Abel Chatenay, for though its habit is far from good, its flowers are so beautiful in shape and colour and of such a delicate fragrance that our gardens would be the poorer without its presence; moreover it is a wonderful autumnal.

In the National Rose Society's Annual for 1922 there is an excellent article on bedding

Roses, giving the views of many well known rosarians on the best dozen. Those of my readers who belong to the Society and are interested in the subject will do well to look up this article, and to those readers, if any, who are not yet members my advice is "Add to your knowledge of Roses, and, by so doing, to the pleasures of life, by becoming a member of the National Rose Society, which has done, and is doing, such excellent work in the cause of the Queen of Flowers."

WHITE LADY.

OLD-FASHIONED ROSES

By Miss GERTRUDE JEKYLL, V.M.H.

THE great number and conspicuous beauty of the modern Roses, which are almost exclusively the ones seen at shows, may give the impression that these and these alone are the kinds worth consideration. But those who truly love their gardens will by no means forget or fail to hold in high consideration the old garden Roses

scent of a cordial quality from the glandular-pubescent growth on the stem and calyx.

The native Roses of France and Southern Europe, known as the gallica group, were taken into cultivation by the French and Dutch early in the eighteenth century. Between the years 1820 and 1830 there were no fewer than 2,500 Roses enumerated in catalogues, chiefly of gallica

The Musk Rose and one or two derivatives are among the most beautiful of climbers, and yet one seldom sees them in gardens, and many places are without a single Sweetbriar. Then, among the quantities of lately produced rambling Roses there is none that for simple garden merit can surpass some of the Ayrshires, the cluster Roses of old arbours and trellises—The Garland,

THE OLD MAIDEN'S BLUSH, ROSA ALBA, IS GENERALLY CONSIDERED A HYBRID OF R. GALLICA.

A SPLENDID WILD FORM OF THE MUSK ROSE WHICH FLOWERED LAST YEAR AT KEW.

of their great-grandmother's time. One has only to think of the beauty and charm of the old Cabbage Rose, *Rosa centifolia*, with a sweet scent that has never been surpassed. It has been in England since the sixteenth century, and, hundreds of years before that, was extolled by Herodotus as the sweetest Rose in existence. This delightful quality is even intensified in its variety the Moss Rose, which has an additional

origin. There is still a number of them well worth growing; one of the best is the bushy double Blush gallica, which is still prized in good gardens. Within the present writer's memory there were a number of gallicas in some of the French catalogues, and as there is a wholesome indication of a revival of interest in the older garden Roses it is to be hoped that they will not be allowed to pass into oblivion.

Ruga, Dundee Rambler and the rest. One side of their parentage, *R. sempervirens*, keeps their foliage neat and glossy, and they do not flout the yards of green, sappy growths that come before the bloom is over and put one out of patience with the *Wichuraiana* ramblers. There is an old climbing Rose named *Flora*, of which we recognise the blooms in eighteenth century pictures, with rather large, full double flowers of a mushroom

the Yellow Banksian, is better worth growing than the old garden Rambler.

The Scotch Broom, a garden variety of the wild Rose, is one that grows in many places. It is a small bushy plant, and comes near the sea, and is often used in several garden uses as well as in the wild. In half-wild places. For sunny walls and for the still no better Roses than the grand Fortune's Yellow, and for a Rose of lower growth, but also thankful for warmth and shelter, R. microphylla, with large, flat double flowers, pale pink shading to a crimson centre and extremely neat, many-leaved foliage.

The Damask Roses are also of the greatest use in borders or separate patches or bays in front of shrubs. Besides the usual red form there is the one with the red splashed with white, commonly but not correctly called York and Lancaster. Then there is the old

Velvet Rose, a half double Damask of a very dark, almost purplish colour, and another old variety of a light pink. Another, that has of late been restored to garden favour, is the old Rome Blanche, or Hebe's Lip. The outside of the bud shews as rosy crimson, the opening flower is a warm ivory white turning to clear white and retaining the bud colour as a thin pootee edge.

The old pink China Rose is one of the earliest to bloom, often in flower before the end of May; it has a second season of good bloom in early autumn and a good sprinkling of flower all the summer. Its variety Cramoisie Supérieure, of brightest, deepest red, is an indispensable garden flower, and the dwarf pink Lawrenceana is one of the most charming of miniature Roses.

THE WILD ROSES

In stem, foliage, flower and fruit the species of Rosa are among the most interesting of hardy shrubs.

BECAUSE perhaps their modest beauty is usually compared with the gorgeous displays made by garden Roses, the wild Roses do not receive the attention from cultivators that they deserve. They should, of course, be compared with hardy shrubs in general, and here some of the species easily hold their own. For bold plantings in the pleasure grounds and open woodland, as specimen lawn shrubs, as bushes or groups of bushes in the shrubby border, and for hedges, few shrubs are more attractive than some of these wild Roses.

In winter how interesting are the thorny stems of *Rosa pteracantha* and *R. Willmottiae*, to name but two, these same two also calling for special mention because of their ornamental foliage. The simple beauty of the flowers may in many

instances be fleeting, yet how charming are the flowers of the Common Dog Rose, *R. canina*, of the yellow *R. Hugonis* and of *R. serrata*, and how can we find words to describe the lurid dark red blossoms of *R. moyesii*. At the time of writing some of the treasures of the outdoor garden are rose hips; those of *R. alpina* in the rock garden, of *R. Davidii* in the shrubby border, and of *R. rugosa* on a hedge are especial attractions. Those whose lot it is to live in country districts will need no reminder of the beauty of the glittering orange-scarlet hips of *Rosa canina* on hedgerow bank and in coppice. We might do worse than use this native plant as a boundary hedge

ROSA WILLMOTTIÆ WITH PURPLISH ROSE FLOWERS.

for the rose garden or in masses in the open woodland.

CULTIVATION.

Select open positions for planting, otherwise one cannot hope for vigorous growths and well ripened wood, which is the foundation for abundant flowers and fruits. A loamy soil is the best, trenching and manuring to a depth of 2ft., though we need not be so precise in its composition and preparation as we should be were we planting a bed of the best Hybrid Tea Roses. It may be urged that it is not necessary to trench at all, considering how freely the Dog Rose flowers and fruits in a poverty-stricken hedge bank. When we bring a plant into the garden, however, we generally try to improve its vigour and enhance its beauty, and most of these wild Roses respond to cultivation.

PRUNING.

This is the word commonly employed, but thinning better describes the process of keeping the bushes shapely and floriferous. It is principally a matter of cutting out the older stems to let in light and air and, incidentally, regulating the arrangement of the branches, for most of the oldest stems are removed to the ground level. This induces the development of vigorous young shoots from the base. Very little, if any, shortening of the growths is desirable, unless it be to shape a lawn specimen or one encroaching on its neighbour. The thinning or pruning must, obviously, be done some time during the winter, after the hips disappear and before new growth commences in spring.

PROPAGATION.

The perpetuation of the species of the genus *Rosa* true to type is a matter of considerable importance. Seeds, naturally, come first to mind, but Roses are so readily cross-pollinated that unless the flowers are protected from insects or

HANDSOME FRUITS OF ROSA SWEGINZOWII.

the fruits gathered from very isolated bushes, the chances are that the seedlings will not come true.

Next on the list is increase by cuttings. A few kinds root readily on a border outside or under cloches in autumn, the majority can be rooted in a propagating case with a little bottom-heat or in a sun frame in late summer, using the partially ripened young growths of the current season's shoots. If this fails we may have recourse to layering, which in many ways is the best, or at least the surest, method of increase. The point may be raised as to why we do not resort to budding. It is practised, but is not a particularly desirable method. There is always the possibility of suckers growing from the base, and we cannot easily get at the base of the wild Rose bushes massed or grouped in the pleasure ground. The cutting out of old shoots to the base always tends to make the stock of budded bushes develop suckers.

A few species, the Scotch Rose, *R. spinosissima* and some others can be freely increased by division of the clumps; while, frequently, using an old spade, pieces can be chopped off with some roots attached.

A SELECTION

of the most valuable species to plant should include the following:

R. MOYESII is the most distinct and valuable of the Roses introduced from China by Mr. E. H. Wilson. At its best this Rose is a vigorous bush up to 10ft. or 12ft. high, producing, in summer, quantities of lurid dark red blossoms 2ins. to 2½ins. across. In autumn is another spell of beauty when the bushes are laden with large dark red bottle-shaped hips. Mr. Wilson describes this Rose as a common bush in the mountain thickets of Western Szechuen at 6,000ft. to 12,000ft. elevation. There is considerable variation in the colour of the flowers. It is the form with the unique lurid dark red flowers which should be propagated by layering. A form with lighter-coloured flowers has been named variety *rosea*, but when seedlings differ so much in colour the giving of distinctive names scarcely seems worth while. *R. Fargesii* appears also to be an extreme form of *R. Moyesii*. There are certainly differences in flower and fruit between the typical forms, but from a batch of seedlings connecting links between the two are easy to find.

R. HUGONIS is one of the earliest Roses to flower, the large rounded bushes 7ft. or 8ft. high and more in diameter being covered with 2in. wide yellow blossoms in May. In growth *R. Hugonis* is a gracefully arching shrub with elegant feathery foliage. It is a native of Western China, and was first introduced by the missionary, Father Hugo, in 1890.

R. DAVIDII.—This is one of the most persistent Chinese Roses in flower and fruit, and was first introduced by Mr. Wilson from Western Szechuen in 1903. In habit it is an open upright-growing bush, 8ft. to 10ft. high, probably more with age. In early summer *R. Davidii* is bright with loose corymbs of rose pink flowers, followed in autumn by pendulous clusters of numerous bottle-shaped scarlet-red fruits ½in. to 1in. long. The variety *elongata* has larger leaflets and 1in. long fruits.

R. SWEGINZOWII is a very vigorous Rose, forming a bush 10ft. to 12ft. or more high. It belongs to the *macrophylla* section and, like the majority of the group, is attractive in flower and fruit. The deep rose-coloured blossoms are at their best in June, and are 1½ins. to 2ins. across. The elongated, pear-shaped fruits are orange red. The plants at Kew were raised from seeds collected by Mr. Wilson in Western Szechuen in 1903. Another attractive species, belonging also to the *macrophylla* group, is *R. setipoda*, introduced

by Mr. Wilson from Hupeh. This has purplish rose blossoms, and red, flask-shaped fruits.

R. OMEIENSIS belongs to the *R. sericea* group with the four-petalled flowers. The variety *pteraantha* is remarkable for the large, richly coloured spines freely borne along the vigorous stems. There are forms with orange red, blood

been written to indicate how much our gardens have been enriched with wild Roses from China during the last twenty-five years.

R. rugosa and its numerous varieties are among the largest of the wild Roses in flower and fruit. The large rounded bright red hips crowned with sepals are very well known on bushes and hedges

THE EARLY-FLOWERING YELLOW ROSA HUGONIS.

FRUITS OF THE RAMANAS ROSE, *R. RUGOSA*.

red, crimson red (var. *atrosanguinea*) and red fruits with thickened yellow stalks. Clustering among the fern-like foliage these are extremely pretty. Unlike most rose hips, the fruits of *R. omeiensis* and varieties fall when fully ripe, often the ground beneath the bushes being thick with fruits.

There are still more of the Chinese Roses, including *R. sertata*, *R. Soulieana* and *R. Willmottii* deserving of mention, but enough has

of this popular Rose, which is a native of China, Korea and Japan.

The Thornless or Alpine Rose, *R. alpina*, is a treasured occupant of the rock garden at Kew. It has rich pink blossoms, but its greatest beauty is in autumn, when the bright red elongated hips are at their best. In addition to the many forms of *R. canina*, other notable British Roses with attractive fruits are *R. mollis* with globose red hips and conspicuous sepals; *R. tomentosa*, with

ROSE GARDEN AND PERGOLA

How to Arrange their Connexion.

BECAUSE the many beautiful climbing and Rambler Roses display their charms to great advantage upon a pergola, there is a natural tendency to associate pergola and rose garden together.

In some cases this is a perfectly easy and simple matter; the rose garden is near the house, and a pergola may be led in a perfectly simple and dignified manner along one side. There are many instances to be seen, however, where either the pergola itself looks sadly misplaced or where the rose garden has obviously been put in an unsuitable position merely to bring it alongside a pergola. In the following notes suggestions will be made for bringing these two important features together in such a way that the rose garden may have the site best suited for the culture and display of the Roses, and that the pergola may be a satisfactory and satisfying garden feature.

The pergola is, in a very special sense, an architectural structure, best not attempted unless it can be carried out in a dignified manner. That is not to say that it need necessarily be constructed of expensive materials or in an elaborate manner. Dignity and over-elaboration have nothing in common. Good and suitable pergolas may be constructed of stone, of brick—in either case with wood cross pieces—or entirely of wood, and the nobility of the material will in no way make up for any deficiency in the design. The tunnels made of "rustic work" which sometimes masquerade as pergolas cannot, of course, be made to look suitable or desirable in any situation whatever. The material of which the pergola is constructed, as well as the degree of finish allowable, will, to great extent, depend upon the construction and finish of the house. This will

especially be the case if the pergola leads away from the house or is, otherwise, placed near to it.

One often sees pergolas leading down the centre of a rose garden. This arrangement is seldom satisfactory, and should never be attempted by the amateur designer, the great difficulty being to embower the rose garden in planting sufficiently heavy to provide balance without rendering the site unfit for the Roses. Remembering that permanent (shrubbery) planting must continue to develop for many years, unless an immense amount of pruning is to be undertaken, and bearing in mind, also, that such pruning—if the desired form is to be maintained—is a task calling for a more than ordinary amount of judgment and knowledge of plant growth, such effects are more than ever undesirable in an age when economy of maintenance is ordinarily a *sine qua non*.

To surround a polygonal rose garden with a pergola is a justifiable expedient, and beyond adequate paths or vistas leading to other parts of the grounds, one which forms an independent feature of itself. It is better in such case to set the pergola upon a slight elevation—not more than one or two steps—or to sink the rose garden a little. Sometimes it is desirable to sink the garden and use the soil excavated to raise the pergola, thus forming a noticeably sunk rose garden. This is not so easy or so simple a matter, however, as might at first appear, because, to make anything of a job, it is necessary to strip the whole of the usable soil from the total area before excavation commences.

The pergola can easily be made an independent feature, too, by causing it to frame an amphitheatre on the north or east side of the rose garden and in a setting of trees or substantial shrubbery.

CRIMSON HIPPS OF ROSA FARGESII.

For its elegant foliage, pale pink blossoms in June and abundant bright red fruits in autumn, *R. Fargesii* forms a tall bush, bearing, as a rule, a profusion of large red fruits. As a lawn shrub *R. sericea* is deserving of more attention. It forms a large rounded bush up to 10 ft. or 12 ft. high with elegant fern-like foliage, creamy white, four-petalled flowers and roundish red fruits.

A rare and uncommon Rose which has attracted some attention at Kew this summer is the dainty *R. myriophylla*, a native of the Southern United States. It forms a graceful bush 2 ft. to 3 ft. in height, perhaps in only 10 years. The solitary purplish rose blossoms are about 2 in. in diameter and open during July and August. The habit of the wild Roses to have brightly coloured hips seems to be lacking in this species, as, this year, two spiny fruits developed without any material change in colour.

A. O.

FIG. 1.—PLAN FOR A PERGOLA ON THE NORTH OR EAST SIDE OF A ROSE GARDEN.

Such an arrangement—one of many—is shewn in plan in Fig. 1 and, very roughly I fear, in perspective elevation in Fig. 2. Rough as the sketch is, however, it should serve to establish the fact that such a pergola is an independent garden feature, which may be isolated—indeed, should be isolated—from other features which have architectural character or sympathies outside the adjacent rose garden.

A straight pergola across one end of the rose garden, unless it leads from some other definitely architectural feature, is apt to look misplaced, but the incorporation of a scendy summer-house or garden pavilion in the design will do much to justify its existence. If the ends can be returned a little, as in Fig. 3, the effect will usually be improved. Here, again, merely to raise the base of the pergola the height of an easy step—say, 5 ins. or 6 ins.—will add much to the dignity of the arrangement.

In any of these cases the use of simple and straightforward stone steps to, and of rectangular paving for, the pergola will make it at once more practical and more sightly. Crazy paving, so often employed for the purpose, is much less effective, but if, on account of cost or for other reasons, it is used, it should be carefully fitted together and the joints made good with cement. The too common method of use, where the stones have cracks between them of from 1 in. upwards, so that they often rock when trodden upon, is far less dignified than any gravel path, and such a pavement has as little to recommend it as "rustic" woodwork.

The colour of the paving, whether red, blue-grey or brown, is, generally speaking, of small importance. Most stones, when used as paving, weather in a season or two to some fairly neutral shade of grey, but there can be no doubt that self-faced York paving, which, by the way, varies a good deal in colour, is the most beautiful stone for the purpose, and at least as durable as any other. Readers who have noticed the hard-textured, homogenous, almost slate-like York stone which is employed in building for steps and sills will wonder how it can possibly be supplied in anything but sawn slabs. The self-faced paving stone is, however, obtained from the laminated strata which overlie the homogenous rock. If York stone is employed, any steps may well be carried out in the same material, hanging the flags over to form a 2 in. nosing. This minimises the risk of anyone "stubbing" their toes when ascending the stairway and, by supplying a line of shadow, adds interest and beauty to the steps. A little thought and extra labour expended upon garden stairways or flights of steps, however short, is commonly well spent, for there is no other garden feature of anything approaching architectural interest which is so generally satisfactory.

Where neither of the foregoing plans seems suitable, a pergola may often be arranged to traverse two adjacent sides of the garden. So arranged it will appear more satisfactorily placed, leaving aside external features which might justify its existence, than if it traversed one side only. The foregoing remarks on paving and on raising the pergola a little will, it is almost needless to say, apply in this case also.

Last of all we come to the case, most frequent perhaps in suburban gardens, where, without breaking vistas or otherwise upsetting the general garden scheme, the pergola, if it is to adjoin the rose garden, must be straight. There is then nothing to do but to justify its existence in that form. An effort should be made to use it as a part of a vista with some proportion, but it will be better to arrange it at one end of such vista rather than in the middle; the vista can then be closed at the pergola end by a seat, which should

FIG. 2.—THE SAME ROUGHLY DRAWN IN PERSPECTIVE.

be dignified, but fairly simple, in character. The degree of elaboration allowable will necessarily depend upon the materials and finish of the pergola, which in turn should hinge upon the lay-out and treatment of the garden as a whole. Further down the vista another feature or other features of architectural interest should be introduced to carry on the feeling conveyed by the pergola itself, and any such additional features should be of a dignity and importance sufficient to afford balance to the pergola. A fairly substantial sun-dial set on an adequate base will often answer, whereas a small bird bath on a dumpy pedestal and without a base will look ridiculous. A little formal paved garden with, it may be, a central pool is commonly an excellent balancing feature, and the same may be said of wrought-iron gates with adequate piers, of a formal and fairly broad stairway, and of an avenue of columnar evergreens, which, if not architectural in fact, is so in feeling. Even a formal herbaceous walk in a setting of Yew hedges will often serve to justify the placing of the pergola.

The construction of the pergola has more than once been discussed in THE GARDEN, and it would not, in any event, be practicable to go into it very closely in an article such as this one, but it may be well to point out that for growing Roses a pergola with elaborate classic pillars is scarcely suitable. Such erections are better lightly draped with Wistarias, Vines and such-like. The very simplest type of pergola admissible, constructed of substantial larch poles with a few inches of the

branches left on is illustrated on page 592. Equally simple in appearance, but a little more formal, are those constructed of squared timber (usually oak); then we have brick structures, which generally look best if constructed with 14 in. by 14 in. bases, stone plinths, 9 in. by 9 in. tops and stone caps, the whole sustaining rough or squared cross timbers. Last of all we have the pergola with stone pillars which almost calls for shaped cross timbers, which should, however, shew axe marks rather than those of the plane. For most purposes the stone pergola is best constructed of coursed rubble walling, the courses being as narrow as possible in reason, but not of equal thickness. Columns 18 ins. or 20 ins. square will, in a pergola of some dimensions, be suitable. Squared stones are, of course, admissible, but they do not afford the play of light and shadow which is so beautiful with roughly coursed work. They are most desirable where the pergola is in fairly close relationship with a dignified home built of ashlar.

A few lines must be written about the planting of the pergola, for without good and suitable planting the best of pergolas is comparable only to a setting devoid of jewels. Near the rose garden the general wish will be to employ Roses very largely, but a little more variety in habit of growth is desirable than Roses will supply. Vines of sorts, Wistarias (almost indispensable) and some of the forms of Clematis montana are especially suitable. The Clematises of lighter growth, such as C. Jackmanni and those of its section, the

related lanuginosae, etc., are best planted against the same pillar as a Rose and, preferably, on the shady side of a pillar. Some of them should certainly be utilised, and it is a matter for careful selection to obtain pleasing colour harmonies between the Roses and the Clematises which make their way among the Rose branches.

The immense popularity of the Wichuriana hybrids has ousted from many gardens not only the older multiflora (polyantha) Ramblers, but the many beautiful Noisettes and Banksias, and Climbing Tea and Hybrid Tea

FIG. 3.—DESIGN FOR PERGOLA AND GARDEN HOUSE.

A VERY SIMPLE PERGOLA IN SPRINGTIME: SCILLA SIBIRICA IN FLOWER.

varieties. This is very regrettable, and place should certainly be found for such sorts as Rêve d'Or, the White and Yellow Banksias, Blush Rambler, The Garland, Hélène, Flora, Leuchtstern, Carmine Pillar, Claire Jacquier, Reine Olga de Wurtemberg and the newer Paul's

Scarlet Climber. These have a quality which is only exceptionally found among the Wichuraiana hybrids. I would include the almost ever-flowering Alister Stella Gray were it not that the variety succeeds as well, if not better, as a free bush. R. V. G. W.

ABOUT WEEPING STANDARD ROSES

THE sight of a well grown weeping standard Rose at the height of bloom can scarcely be surpassed in any garden, but, perhaps on account of the dazzling effect, it is necessary to exercise the utmost care in the placing of such specimen trees. Here and there on a lawn, planted in a circular bed 4ft. to 6ft. in diameter and with a dark background, such standards look at their best, but avoid training a lawn with circles of them all round the outside edge. Used in this way, as specimens, a row of Dwarf Polyantha Roses round them makes a good effect; but give the standard plenty of room, otherwise the Dwarf "Polys" will get little chance to grow.

Another use for them is on similar lines to a pergola—a "weeper walk," leading from one part of the garden to another; but the "walk" should be at least 12ft. wide, for it is surprising how much room a well grown weeper takes up, and ladies' fragile dresses are expensive items to replace if torn by the thorns of a pair of extra corpulent weepers.

Here, we have also grown a row of weeper, as a boundary between two parts of the garden, in which case we run a rope or chain from stake to stake, tying only a couple of shoots to each, and it is surprising how quickly it develops into a festoon of Roses.

Digressing for one moment, on the subject of the best material for such ribbon connections, we formerly used old ships' rope, but it has two faults: one, that it sags, making the festoons hang lower and lower; and the other, an even worse fault, is that it lets you down, for the rope rots, a high wind breaks it, and irreparable

damage is done by the best shoots of the plant being torn out.

Chain is unsatisfactory on account of its weight, which necessitates extra stout stakes, and, also, Roses do not like metal—it is too cold for them in winter and too hot in summer. It hardly affects old wood, but with these weepers only the new wood should be tied in, and, when tied to metal, a hard frost will often kill a new shoot. The best solution of the difficulty we have found is to use electric cable about as thick as a lead pencil. Large quantities of this are being disposed of as surplus Government stores, and a mile of it can be purchased for less than a couple of pounds.

As to treatment and growth, standard weepers should be strong enough to grow naturally, *i.e.*, without being tied to any umbrella support. The Rose should throw sufficient new shoots each year, each reaching the ground, and when in bloom completely hiding the briar stem. Liberal treatment by a thick dressing of manure, in spring, well forked in and a few cans of liquid manure should give the desired result in growth, provided, of course, the plant was a good one originally and properly planted, with plenty of organic food for its roots to get at.

Most of the Wichuraiana Roses—practically the only suitable type for weepers—throw their new shoots from the base, in which case *all* the old wood should be cut clean out; but some varieties, such as Albéric Barbier, Delight, etc., also throw new laterals from the previous year's shoots, and, when pruning, these laterals should be cut back too.

To class the best varieties fairly in order of merit one can only go by one's own experience, and, admittedly, varieties that succeed in one

locality are not at home in another. Situation, aspect, soil, treatment and the plant itself all may vary considerably, so the following varieties are described by their growth in an open garden on the hills in Surrey and on a light, sandy loam soil.

For all-round excellence there is nothing to beat ALBÉRIC BARBIER. The growth is wonderful, it blooms early in the season, and retains almost all its foliage through the winter. Five years growth here has transformed the weeper practically into a balloon, and the briar stem, of which the girth is always indicative of the quality of the tree's growth, is 3ins. in diameter.

Secondly comes EVANGELINE, also a massive grower, but a later bloomer. The fragrance of the single pink blooms is delightful, and scents the garden for many yards round. A hint, however, in regard to pruning this Rose—it is a shy bloomer on new wood, therefore leave some of the one year old shoots cut back slightly.

Our third favourite is FRANÇOIS FOUCARD, also a strong and clean grower, with lemon yellow flowers, blooming early.

So much for the perfect varieties, which we regard here as leaders, while the rank and file we put into two categories, classifying them as excellent or only good. The excellent ones are:

LADY GODIVA, pale pink, late flowering.
DOROTHY PERKINS, darker pink, late flowering.
RENE ANDRÉ, yellow, early flowering.
CORONATION, crimson, splashed white, late flowering.
EXCELSA, scarlet, late flowering.
SHOWER OF GOLD, yellow, early flowering.
JERSEY BEAUTY, pale yellow, early flowering.
JOSEPH LAMY, white, with pink edges, early flowering.
WHITE DOROTHY, white, late flowering.
FRANÇOIS JURANVILLE, salmon pink, early flowering.
MINNEHAHA, deep pink, late flowering.
DEBUTANTE, pink, midseason.
GARDENIA, bright yellow, early flowering.
SANDER'S WHITE, pure white, late flowering.

The illustration of this beautiful Rose is of a one year old plant; too short a period, of course, for the plant to have attained anything like perfection.

As good growers, though, by comparison, not so good as the above mentioned, we have

DIABOLO, fiery red, early flowering. Not a true Wichuraiana; in fact, it is classified by some nurserymen as a Hybrid Perpetual. It grows wonderfully strong, but is a scarce bloomer.

DR. VAN FLEET, pale pink, midseason. Also very strong, but too inclined to run to growth and foliage without a corresponding profusion of blooms. Counterbalancing this objection, however, it is sweetly scented, and the blooms remind one of miniature trusses of Mme. Augustine Guinoisseau.

CHATILLON RAMBLER, shell pink, late flowering. Unfortunately, it is disinclined to throw new shoots from the base, preferring only to throw laterals, with the result that the heads get very bushy and top heavy.

ROMEO, dark red, late flowering. The blooms are larger and darker than Excelsa, but here again the quantity of blooms is not in proportion to its strong growth: in fact, it is a real shy bloomer. Perhaps by leaving in some of the old wood it may bloom better.

LIONNE GÉRAISI, salmon, early flowering. The growth of this is "sprawly"—apt to run to laterals instead of clean new base shoots.

FAMILY GRAY, yellow, early flowering. This promises well, but we have not grown it for a sufficiently long time to express a decided opinion on its merits as a weeper.

HIAWATHA, crimson late flowering, is always an unknown quantity as regards growth, and is quite as likely to do better when absolutely neglected and left to itself than if tended and fed. Here, the heads are bushy, and we cannot get the essential long trails of growth for the next season's blooms.

ETHEL, flesh pink, early flowering. A very pretty shade of pink, this is always a favourite with the ladies. Growth is not very strong, but the plants thrive.

MRS. M. H. WALSH, white, late flowering. Here, again, growth is sacrificed for prettiness. The shoots are thin—almost wisps, but plenty of them, and being a profuse bloomer the head is like a bridal bouquet when in full bloom.

FLAME, fiery pink, late blooming. When in full bloom it well merits its fiery name, but, unfortunately, it suffers badly from mildew, and to keep this down it must be frequently sprayed early in the season and during the blooming time.

SWEETHEART, pale pink, late flowering.

DELIGHT, carmine, late flowering. Both of these are bushy growers; the heads are good, but they are not ideal weeper types.

We now come to—what *not* to grow as weepers, and we must eliminate at once the stiff-growing varieties. American Pillar, Blush Rambler and Grüss an Teplitz are all erect growers which cannot weep or trail naturally, and if they are to be forced into an unnatural habit of growth, leave them alone. Even Paul's Scarlet, beautiful and profuse bloomer though it is, cannot be persuaded to weep, and here our plants send stiff shoots up skywards. To grow these stiff-growing varieties as standard weepers is surely unnatural; they

look, in fact, like porcupines stuck on broomsticks. Of new varieties we are experimenting with the latest climbers produced and testing them all as weeping standards, e.g., Irene Bonnet, Lacotte, Violetta, Albertine, Yvonne and Snowflake. The latter particularly looks most promising, with its snow white flowers and wonderful foliage.

Oxtd.

HERBERT L. WETTERN.

[Mr. Wettern has probably tried as many Ramblers as weeping standards as anyone, and the culture which he gives to Roses is well known. He possesses, too, a soil which is excellent for this class of Rose, and, altogether, most readers will think that he has been far too modest in his claims as to the value in other districts of his experience and experiments at Oxtd. There is plenty of room for new varieties with a vigour approximating to that of Alberic Barbier, which at present stands quite alone as a sort for weeping standards. These "weepers" are, we feel, in some danger of going out of favour owing to the way in which they are abused in many gardens. Spottiness in planting is an evil not always easy to avoid, and weeping standards specially lend themselves to it. They are, in general, most effective when used to form an avenue, as centrepieces for beds of the Dwarf Polyantha varieties, or when arranged in groups of from three to seven of one variety. When grown in groups the plants lose something of the symmetry we usually associate with the weeping standard, but the group as a whole should be moderately symmetrical and, as every gardener knows, there are places where plants on "legs" are practically essential. These weepers are truly beautiful when in blossom.—Ed.]

A TINY JUNIPER

SO admirably suited to the rock garden is that delightful little conifer *Juniperus hibernica compressa* that no rockery planting should be without it. It is exceedingly attractive with its bluish grey foliage and its always uniform shape, which takes the form of a very dense column tapering to a point and which, by the way, needs no artificial training to retain its shape. It is very slow growing, which is, undoubtedly, its greatest attraction as a plant for the rock garden. Generally speaking, the growth it makes in a year is about an inch, therefore it is usually possible to calculate the age of a specimen within a few years. I am afraid that a number of rock gardens are spoilt by the use of quick-growing conifers, probably bought when very small and attractive. *J. hibernica* is not a common plant by any means, which is due largely to its slowness in growth. It may be propagated by cuttings or grafting. Personally, I prefer the former, although it takes longer to get a good plant, but when one has got a nice plant the delay is well repaid. Cuttings may be safely put in in October. They should be placed in a frame and, if possible, under a hand-light in the frame. The mixture I suggest for cuttings is one part of sharp silver sand and one part of charcoal (broken up finely). Water should be given sparingly throughout the winter months, and when April arrives the cuttings should be rooted and fit to put into small pots, in which they should remain until they are large enough to be planted out, which will take two years at the least. As regards their position in the rock garden,

A ONE-YEAR STANDARD OF ROSE CORONATION AT OXTED.

ANOTHER YEARLING STANDARD; THE VARIETY IS SANDER'S WHITE.

this should be well thought out; in fact, it is quite an art to be able to place dwarf shrubs where they lend their best appearance. One of the most pleasing positions is to be found where some great boulder lies immediately behind. Wherever planted, however, no plants of similar height should be allowed near, or the beauty of the Juniper will be lost. The space around

should be planted with neat carpeters, such as *Arenaria verna*, *Ranula australis* and *Myosotis rupicola*. Our little Juniper enjoys a sunny aspect in any good ordinary soil, and is a lover of lime. The typical Irish Juniper (*Juniperus communis hibernica*) is, when quite young, very similar in appearance, but it soon grows to a tree several feet high.

F. BARKER.

GARDEN DESIGN—III

Gardens of Shrubs

ALTHOUGH in its results often very uninteresting, the shrub garden ought to be one of the most beautiful parts of the grounds. Unlike herbaceous borders, the shrub garden can be interesting all the year round with a beauty of form which must be lacking with herbaceous stuff. Their wonderful difference in habit of growth and their more permanent nature make shrubs the most adaptable of materials with which to create beautiful effects.

In every part of the garden there should be felt that proportion and delicately adjusted balance which is in its results so pleasing to critical taste, and this should be particularly so in gardens made of trees and shrubs. One can plant, for a certain effect, the designer's conception of the garden as he wishes it to be. Japanese influence can often be felt in this sort of design. With the use of the most suitable materials in the most artistic way, the careful choice and placing of every plant and shrub is necessary if its proper relation and value in the ultimate scheme is to be obtained.

To a large extent, what makes such a garden more a work of art, requiring greater skill in its making than other parts of the grounds, is that the whole thing is, or should be, accurately proportioned, with a properly balanced harmony of curves. The lawns should be hollowed in varying curves, the lines of which definitely connect and continue the lines of the planting which bounds them, and they should, moreover, emphasise the glade effect which can be made so pleasing a feature in this part of the garden.

In such a garden as this, where every plant and mass of plants tells so exactly in the general scheme, unusual care must be taken in pruning. If the planting is to develop in the best way, not only must the several peculiarities of the different shrubs be studied and each treated so that it grows to its proper size and shape, but, without impairing their flowering or spoiling their inherent beauty of form, each group and each plant must be so pruned that, ultimately, they provide just the necessary weight and the size and shape wanted in their particular place. Even good gardeners usually need skilled super-

vision for this work, but if the work is properly done the results will be so beautiful that they will far more than repay the extra care.

The yellows and golds of the Berberis with their rich green foliage; the wealth of blossom on Almonds, flowering Apples, ornamental Plums, Cherries and Peaches in every shade of pink; the gorgeous and varied colouring of Azaleas; the different Spiraeas, all almost equally charming and with an unmistakable family likeness; the native and hybrid Brooms, white, cream, gold, brown, chocolate and wine pink; Gorse; Forsythias; Laburnums and Lilacs, and the hosts of other plants offer materials enough to give as much colour and as many harmonies of form as could be wished for.

Many of the better-known shrubs and smaller trees flower in spring and early summer, but there are a number that come into bloom later in the year, and such a garden as I am describing need never, except in the quite late autumn and winter, be without plenty of colour. Later in the year, after the spring and early summer flowering trees and plants have ceased to flower, there will be Roses—the yellow-flowered *Rosa Hugonis*, *R. Moyesii* (deep red) and others, such as *Aglæa* (yellow), *Félicité et Perpétue*, *Crimson Rambler* and *Tea Rambler*, if planted in fairly rich soil and allowed to grow as they like, will make great mounds of growth covered in July and August with flowers. On dry, warm banks and in rather sheltered places can be masses of *Rock Roses*; these must be towards the front of the borders, and in the sunniest places with rather poor soil they will give wonderful stretches of colour for a long time. Established plants that flower early should have their dead flowers removed, and they then will continue to bloom freely.

Stortium junceum, planted rather back because of the tall upright habit of growth, will give splashes of strong yellow at midsummer and later, and *Eucryphia pinnatifolia*, the roots of which need shading from hot sun, is another shrub that should be planted for the beauty of its flowers at this season of the year.

On banks or in spreading masses towards the front of the borders may be planted varieties of hardy Fuchsias in as large masses as space will allow. These should have plenty of sun, but not too dry a root-run. A large boulder of stone placed here and there among them will, as well as giving that coolness and moisture always imparted by stone, add to the well-being and consequent beauty of the plants.

A garden of trees and shrubs should be a garden of curving lines. Subject to the necessary pruning, almost every tree and plant that grows is, if allowed to develop naturally, in itself a thing of beauty. There are, however, certain rules that should be observed. Backgrounds should be as dark as possible, for almost every plant and flower is seen to better effect against a dark setting but in a good light. To realise this one need but think of flowering Plums, Almonds, Apples or Cherries against dark Pines or Firs.

The nature of any planting will depend very much upon the character of the surroundings. One may have a lovely and gracious garden merging almost imperceptibly into its surroundings or, on the other hand, one may plant new or use existing backgrounds of trees or hedges, making with them a definitely enclosed garden. There are plants in plenty; it only needs the artist's sense of mass and line to make with them the most beautiful scenes.

Nearly all the Berberis family may be massed in generous groups, the dwarfier sorts especially, such as *BB. Thunbergii*, *Wilsonæ* and *empetrifolia*, and others of more recent introduction, are

SCENE IN AN ESSEX GARDEN MADE BY THE WRITER.

especially beautiful planted in this way. This applies equally to most of the dwarfier-growing Gorses and Brooms. Of these, *Cytisus kewensis* and *C. purpureus incarnatus* are prostrate or semi-prostrate in their habit of growth. The soft grey cushion-like growth of *Genista hispanica* are also very pleasing. Other varieties of *Berberis* always worth planting are *B. aggregata*, very

procumbens is most useful for the way in which it may be used to cover the ground and to overhang rocky faces. *Juniperus communis hibernica* is a dwarf form of columnar growth, valuable for the way in which it may be used to emphasise points in design.

The plan given shews a portion of a glade bordered by trees and shrubs chosen for their

PLANTING PLAN FOR A SHRUBBY GLADE.

like *Wilsonae*, but more vigorous; *B. brevipaniculata*, another Chinese species of outstanding merit; and *B. dulcis* and *dulcis nana* form rounded evergreen bushes small enough for a tiny garden. *Berberis polyantha* is more free in habit, attaining a height of 7ft. or 8ft., while the strong-growing *B. stenophylla* and its varieties are all of a very pleasing habit, most of them throwing out arching sprays. Of these *stenophylla* forms, *gracilis* and *Irwinii* should be in every shrub garden. In larger gardens the common *Berberis vulgaris* and its purple form should be planted well back in the borders. They provide a wealth of coral red berries in autumn.

Indispensable, too, and adding very much to the character of such a garden as we are describing, are the *Junipers*. As a family the *Junipers* are some of the most useful plants we have, and that in several ways. *Juniperus chinensis* is a strikingly beautiful golden Conifer of upright growth, and there are several distinctive prostrate or semi-prostrate forms. *Juniperus japonica aurea* is a good golden shrub. *Juniperus Sabina prostrata* with its grey-green foliage is one of the best of the quite prostrate forms, and *J. Sabina tamariscifolia* is a more vigorous but equally useful variety. *Juniperus tripartita* is another vigorous dwarf shrub of spreading growth, and *Juniperus*

habit of growth, as well as for the beauty of their flowers. Firs and taller standard and half-standard *Laburnums*, *Pyrus* and other flowering trees are arranged to form a background and so make of the glade a separate garden.

For such planting the ground should be thoroughly trenched and moderately manured with well decayed stable or farmyard manure. Drainage should be attended to if required, but this is seldom necessary for ordinary soils. On any but cold wet ground, planting should be done from now onwards, as early in the winter as possible. Care should be taken when planting to spread out the roots and work between them fine friable soil. On heavy ground it is not advisable to plant in wet weather, as it is difficult to make the plants sufficiently firm without consolidating the soil too much. On dry days the roots should be kept covered with soil or some damp packing material, so that there is no risk of their drying and the fibrous rootlets consequently perishing.

On a larger scale such planting could very well be used to border drives; very beautiful effects could be obtained by the proper spacing of some such planting combined with the judicious use of specimen trees. I hope to deal with this in a later article.

PERCY S. CANE.

BULBS FOR HANGING BASKETS

ONE seldom goes into a greenhouse in summer, be it ever so small, where some attempt is not made to enhance its attractions by a well filled basket or two, from which hang beautiful foliage wreathed by no less lovely flowers. If the house is a warm one, it is very easy to carry on this delightful feature all through the winter and spring by a succession of baskets filled with suitable plants.

When, however, it comes to a question of the house that is only heated to exclude frosts, the problem is apt to be regarded as impossible of solution and, beyond a basket or two of hardy Ferns (minus the fronds), nothing is attempted. One is very tempted to ask, "Why?" Really there is no reason at all. In view of the large

numbers of charming spring-flowering bulbs that flourish under basket culture (or as "balls," of which more later), there is no reason why that roof should be one whit less attractive or gay with vivid colour than during summer and autumn. All that is required is a good number of wire baskets, a supply of soil, plenty of fresh green moss and suitable bulbs.

The filling of the baskets is so simple that it may be dismissed in a few words. Do not fail to line the baskets thickly with moss. Neglect in this direction will allow a great deal of soil to wash away when the necessary watering is done. The soil itself also merits consideration. While it should be light, rich and sandy, it ought not to be forgotten that baskets, unlike pots, are exposed to evaporation over the whole of their

surface and that a good quantity of moisture-retaining material, such as peat, is an excellent addition. Bulb roots take extremely kindly to this, as evidenced by the remarkable success of bowls when filled with peat fibre, and we do well to add about one part of rough peat to every two parts of light soil. Till the baskets quite full, but do not make the soil firm until the bulbs have been inserted, then press well down and, if necessary, add a little more soil to make up. With baskets, one does not, of course, plant only on the surface. Between the moss all round the sides, as well as the top, should be thickly planted with bulbs, pressing these deeply into the moss and earth.

After tilling, the next important point is to ensure thorough rooting, a condition that is best reached by placing the baskets in a cool shaded corner out of doors. It is important to keep them cool, shaded and moist, so that slow, thorough and abundant rooting is ensured, for that is the only foundation upon which success is laid. It is better in any case not to bring them inside until after Christmas has turned. A great point is to keep them evenly moist, especially after they are brought into the greenhouse, and care must be also taken to hang them in a very light place so that, all sides of the basket being evenly illuminated, development is correspondingly equal.

The "balls" mentioned above respond to similar cultural details, and the only difference is that a ball of peat is first made up and roughly tied here and there with copper wire before the bulbs are inserted over the surface. These can be kept outdoors and moistened when required by dipping into a tank of water.

Now as to suitable kinds, for, naturally, some kinds are better adapted to our purpose than others. It is not only dwarf sorts that should be employed, although the greater number should be dwarf, especially where it is intended to hang them in small or medium-sized houses. For a lofty conservatory, however, a basket of the wonderful Parrot Tulips should be tried. This idea has not, it is true, the merit of novelty, but the gorgeous effect of these immense flowers with their daring colouring and fascinating feathering and laciniation is unique, so that it will bear repetition. A special favourite of my own in the bulb-baskets line is one filled by that wonderful *Muscari Heavenly Blue* or the white variety *botryoides album*, known sometimes as *Pearls of Spain*. Normally, the height of these is about 6ins.; but under glass the stems are a little longer and they do not grow upright, but both leaves and flowers arch over and form almost a ball of blue or white flowers. Crocuses of all kinds give splendid balls of colour, and when thickly planted the flowers of these are so closely set together that one scarcely sees the green moss from which they spring.

In making up these Crocus baskets one should not confine one's choice solely to the stronger colours. The effect of the lovely pale mauves and striped varieties, to say nothing of the pure whites, is exquisite, as is also the added effect, when, in warm sunlight, they expand just enough to shew the orange anthers in the centre. Snowdrops cannot be recommended, as they do not take kindly to basket culture, but the Snake-head *Fritillaries* do well and make a most unusual picture with their drooping queerly chequered bell-like bloom. These, though not early, are very easy if one does not try to push them too hard for the sake of earlier flowers. Roman Hyacinths, on the contrary, are early and among the most suitable for our purpose, for their spikes are both light and graceful and they follow the first blooming by a subsidiary spike or two. BULBIST.

FURTHER NOTES ON THE GREAT AUTUMN SHOW

Most object in going to the Holland Park Show was to see Michaelmas Daisies, and although the season was on the late side, I was not disappointed. As I walked up and down the gay portico seeking what later on I might devour, or, to be more accurate, what I might offer as food for my empty note-book, I came to the large and interesting display of Messrs. Dickson and Robinson of Manchester. I had no idea before that they were such Michaelmas Daisy people, but now I have one more name to add to my list. Their exhibit took my eye because of the brave show it made in a dark corner and because it included a number of varieties which were quite new to me. Poor things, they were frightened when the rain came on, and a great gloom filled the already gloomy hall. The cry of Persephone seemed to reach my ears:

"Oh, light, light, light," she cries, "farewell.
The coal-black horses wait for me.
O shade of shades, where I must dwell,
Demeter, mother, far from thee!"

And they came from Manchester! They were reassured when they saw that, after all, they were only going into Jacob's note-book. Walkden's Pink took my eye more particularly. I suppose because I am on the look-out for pinks and roses. Of the other good Daisies that attracted me, both here and elsewhere, I have already written, so I pass on to what to me were the etceteras of the occasion. I had hoped for some Nerines, but beyond a few Fothergillii major in Wallace's exhibit and two or three which looked something like Bowdeni in Reuthe's, the Show was drawn blank.

Where, had I been given a golden apple to lay at the feet of the fairest, would it have been placed? On Mr. James MacDonald's flawless lawn of well ordered grass beneath the delicate pink-tipped sprays of a 3ft. high ethereal-looking plant labelled *Tricholena rosea*. Something of what *Thalictrum dipterocarpum* is in the flowering plant world, this is in the world of Grasses. The host of delicate little pale rosy lavender parachutes suspended in mid air by fairy threads have been changed into a milky way of tiny rose-tinted stars kept in place by almost invisible hairs. The name was well chosen, for "Tricho" means hair; but, alas! the long-lasted botanists have thrown it over, as we learn in Nicholson, and now it lives in the big sea of Panicle, of which the synonym appropriately enough is *Thalassium*. *Tricholena*

rosea is an animal and, I think, hardy. It is well worth enquiring about.

I fancy the appreciation of autumn tints, whether of leaves or berries, is a growing taste, and I have no doubt the announcement of the Show, which specially mentioned these things, drew many visitors. There were two beauties there. One was evidently a sport or seedling form of our old scarlet-coated friend *Berberis Thunbergii*, but the branches had a more erect habit of growth and the colour was more intense. This appeared among Messrs. Cheal and Sons' fine collection of berries and foliage. The other was one of the innumerable Japanese Maples which we all know provide us with many glorious sights. None excelled in richness *Acer japonicum laciniatum* in Messrs. Hillier and Sons' large group with its toothed palmate leaves of deep crimson, not unlike the colouring of a hand-polished "mahogany" round which more generations than one have enjoyed their nuts and wine.

One of the advantages of these shows is that one meets so many friends there. Certainly I was lucky. I wanted to hear about the progress of the new *Gladiolus primulinus* hybrids, so who should I come across but Mr. G. W. Leak (R. H. Bath, Limited, is his professional name) and Mr. J. L. Gibson (Lowe and Gibson). Each firm had exhibits, and each exhibit had numerous examples of those very lovely hand-made flowers—the *Gladiolus primulinus* hybrids. Both my friends are

A CHARMING PINK GRASS, *TRICHOLENA ROSEA*

a little "gone" in this direction. So am I. Three men in the same boat! I saw *Nydia*, delicately complexioned and so sweet—a leading lady among the new-comers, as the bright scarlet-coated Woodcote is a leading gentleman. Dahlias, as might be expected in the previously frostless autumn, were plentiful and of many shapes and sizes. Cheal's Stars are all good, but on this occasion I was most attracted by Mauve Star, as I was by the dwarf bedding Cactus variety *Marianne* of Messrs. Carter, Page and Co. *Scabiosa caucasica* has come to be closely associated with the firm of Isaac House and Son of Westbury-on-Trym. They have worked wonders. The original has been transformed both in colouring and in size. My pick of the long white show tiers was *Nellie Dow*. It was dark enough to be novel and pleasing, and sufficiently regularly irregular in the disposition of its ray petals to be specially attractive.

JOSEPH JACOB.

ROOT-PRUNING FRUIT TREES

CERTAIN fruit trees, especially those of Apples and Pears, will, in some soils, grow year after year without bearing fruit profitably. The annual pruning of the shoots does not have the desired effect; in fact, in many instances it results in increasingly vigorous growth which cannot ripen satisfactorily in our climate.

Judicious root-pruning will, in the majority of cases, do much good. Those trees with attenuated shoots which do not bear fruits satisfactorily are, of course, not benefited by root-pruning. What they require is root feeding. The proper time to root-prune is from early November to mid-February in northern counties and from the middle of October to the middle of February in the southern. The trees most suitable for root restriction are those from four to sixteen years of age. With some exceptions older specimens are not benefited much and the labour is great. Young trees may be entirely lifted, have their roots pruned and be replanted with the best results; but the roots must not be allowed to get dry before the tree is planted again. The entire work on each specimen should be done and the replanting finished before another tree is interfered with. Trenches should be opened round older trees: 2ft. 6ins. from the stem in the case of trees seven to ten years old, and 4ft. distant in the case of specimens from ten to sixteen years old. Up to twelve years of age the trench may be made all round the tree, but it should go only half way round in the case of older ones, the remaining portion being dealt with the following winter.

A fruit tree possesses three kinds of roots, namely, tap-root, wood or fibreless roots and fibrous roots. When the tap-root and the fibreless ones permeate the soil, the first to a considerable depth and the second in every direction from the stem, the result is that many strong shoots grow annually. The trench should be about 18ins. wide to enable the workman to get at the lowest roots—the fibreless ones—and those crossing the open trench should be cut off, using a sharp knife where possible. If large, they may be sawn off and the ends smoothed with a sharp knife. All fibrous roots found should be preserved. When the trench comes to be filled up, if any gritty loam is available, it should be mixed with the ordinary soil. Make all quite firm by treading as the work proceeds. Do the root-pruning and shifting of the soil while the latter is fairly dry, as this partial dryness is essential to success. Success means that in the immediate future the trees will make less wood, but more flower-buds will form, the spurs increase and with them the crops of fruit.

GEORGE GARNER.

CORRESPONDENCE

THE SNAKE-ROOTS.

I WAS well pleased to read "W. L.'s" seasonable note on the genus *Cimicifuga* (page 563). As he justly remarks, it is strange that these beautiful autumnal flowers should not have earned more general favour from amateur growers of hardy plants. It is still more strange that such an enthusiast as the late Mr. Reginald Farrer should have written in disparagement of the family. "The *Cimicifugas*," he wrote in his "Alpines and Bog Plants," "never attract me very much . . . they have something a little coarse and rank about them, to my taste—perhaps a hinted warning of the poison that lurks in all their being . . . the *Cimicifugas*, like their rare native cousin, *Actæa spicata*, are too unmistakably ominous in appearance to have the full attraction of their beauty." After all, we do not aim at stocking our flower borders with esculents. If poisonous properties were held to rule out plants that possess them, away would go *Aconites*, *Colchicums*, *Foxgloves*, *Rhododendrons*, even our beloved *Christmas Roses* and a host of other things bright and beautiful. Farrer specifies *C. davurica* as the handsomest of the genus, but in my humble judgment those who grow *C. racemosa* and *C. simplex* have got the pick of that basket.—HERBERT MAXWELL, *Monreith*.

THE FLOWERING CURRANT.

I CANNOT help wondering why so many present-day writers on flowering shrubs affect to despise the Flowering Currant, *Ribes sanguineum*. True it cannot be called choice, inasmuch as it is to be seen in many and many a suburban garden, being almost as ubiquitous as *Rose Dorothy Perkins*. I sympathise with those who tire of "Dorothy"; she is very showy, but a trifle blatant and vulgar, whereas the Flowering Currant is neither the one nor the other. There are, of course, many forms of the plant, and having obtained a specially good one it behoves us to increase it from cuttings, though if only the deep-coloured forms are grown, the seedlings which usually come up in great numbers under pergolas and other places frequented by birds do not often fall away appreciably from the parents.—N. H. P.

LILIUM REGALE.

WITH reference to the note on this subject from Mr. J. H. Watson which appeared in your issue of October 20, I am of the opinion that many have not yet realised the possibilities of this exquisite Lily. I have, for example, a batch of bulbs which has not been disturbed for eight years. These bulbs have gone on improving from year to year until this season, when they gave results which surely cannot be rivalled, and which, I think, must be the limit of this Lily. I had many bulbs with two and three stems and

one with four stems. One bulb gave me a stem with thirty flowers. The soil—which is in East Lothian—appears to suit the Lily, but the bulbs receive a liberal top-dressing every spring with decayed grass mowings and leaves. Some of the stems were 7 ft. high. My bulbs were raised from seed. I have a batch of 2,000 seedlings now in their second year, and most of them should flower next season. The roots of this Lily must have shade—mine are among *Rhododendrons*—and they must not be disturbed. I am looking forward to next season's results, and my only regret is that I did not have the plants photo-

A GOOD FORM OF THE FLOWERING CURRANT, *RIBES SANGUINEUM*.

graphed this summer. I had been away from home and when I returned the Lilies were just past the zenith of their beauty. The fact of this *Lilium* flowering when the roots are three years old causes me to wonder what bulbs—properly grown and undisturbed—will do when they attain the age of ten years.—GEORGE M. TAYLOR.

THE PERIWINKLES.

IN addition to the uses made of these plants by "G. G." and noted on page 515, may I add how they are employed here? *Vinca minor* is used as an edging plant to a bed of blue and mauve shaded flowers, while *Vinca major* clothes a steep bit of bank which happens to back part of a flower border. Both varieties are also made use of

rather extensively in the way mentioned by "G. G." as a carpeter in other parts of the grounds here. As a bordering plant *Vinca minor* is quite good and looks uncommon so used, besides being green at all times and pretty when in bloom. Its free habit of growth makes clipping back a necessity at least twice a year if neatness is desired. When attempting to get the lesser Periwinkle established for the purpose I have described, it should be planted somewhat thickly and the longest shoots pegged down. So treated, these shoots soon root and an edging quickly forms. The flowers of *V. major* are distinctly handsome, but the growths are of no use for cut flower work because they flag terribly, presumably owing to their very sappy texture.—C. F., *Amphill Park*.

DIANTHUS MICROLEPIS.

IN the wide range of alpine Pinks there is none which appeals more highly to the lover of the more minute gems of the mountain flora than *Dianthus microlepis*. It would appear that many find some difficulty in its cultivation, but with the writer it was by no means troublesome if given a little attention now and then in a rock garden. Now, the more erudite modern cultivators recommend the moraine for its home. It is, undeniably, very happy there, but it is not everyone who possesses such a capital abiding place for the choicer alpine, and it is well to consider how this precious little flower can be otherwise provided with its requirements. It is worthy of considerable care, so lovely is its tiny mat, rarely more than 6 ins. in diameter, of short broadish leaves. From this mat rise, hardly clear of the foliage, its miniature flowers of starry form and pink or white in colouring. It is, verily, a precious gem of the rock garden or moraine. One need say little about its treatment in the moraine, but it should be planted, for preference, I consider, in the higher parts if an underground water supply is provided. I think a little lime about it, should this not be included in the material of the moraine, is welcome. In the rock garden it wants a thoroughly well drained, light soil composed of loam, sand and leaf-soil with plenty of grit in about equal proportions, but a little more or less of any ingredient will not matter

much. I always made a point of planting it on a level portion, working a little fresh compost of the same material among the leaves in spring and autumn, and not forgetting a soaking of water in dry weather. Soft water is preferable, but I have had, necessarily, to use hard at times and have done so without causing apparent injury. Spring is the best time to plant this exquisite *Dianthus* and its form *Freyii*, which is also charming.—S. ARNOTT.

THE FIFTY BEST ALPINES.

PERHAPS no phase of gardening has gripped the public taste and made such rapid strides in favour with the great majority of garden lovers as the culture of alpine plants. Rock gardening

intense into calm, as, within a comparatively small space, a representative collection of alpine plants can be accommodated typical of the flora of many countries. Through the untiring efforts of enthusiastic collectors so many beautiful and charming plants are now available for this most interesting hobby that it is a difficult problem indeed to draw up a list of the best fifty alpine. One has to eliminate so many choice and attractive favourites that the difficulty is not which to include, but which to exclude. Consequently, your correspondent "Purley" on page 546 has set a rather difficult task before those who have the temerity to write down the names of their best fifty. In the year before the Great War, similar lists appeared in the pages of *THE GARDEN*, compiled by, among others, the late Reginald Farrer and Mr. S. Arnott. Looking over these lists and comparing them with "Purley's," I was interested to find the latter had only nine names on his list of fifty which were included in Mr. Farrer's list, and only eight which Mr. Arnott had on his. In the three lists I have before me, which appeared ten years ago, I find only fifteen names mentioned which appear in "Purley's" choice. So much depends on individual taste as well as difference of locality—some plants succeeding splendidly in one place and proving worthless in another—that, in making a selection of the best fifty, there will obviously be a wide divergence in the varieties chosen. This being so, one hesitates to criticise "Purley's" list, which, however, contains several names I should not myself include in so small a selection. For instance, I would not place *Aquilegia alpina* on the list to the exclusion of *A. glandulosa* as grown and exhibited by Mr. Clarence Elliott; *Dryas octopetala*, although a beautiful little native, is scarcely worthy of a place among the best fifty; *Papaver alpinum*, too, is scarcely quality for so good a position. *Petrocallis pyrenaica* has always been a little weedy in appearance with me and, consequently, must drop out. In the hope, however, that it may be interesting and helpful, I venture to append a list of what I consider the best fifty, including as wide a range of variety as possible, although at the same time feeling that I am excluding fifty perhaps equally as good. *Ethionema warleyensis*, *Androsace sarmentosa* Chumbyi, *Anemone Pulsatilla*, *Aquilegia glandulosa*, *Arenaria balearica*, *A. montana*, *Campanula Portenschlagiana* (*muralis*), *C. pulloides*, *C. punctata*, *Dianthus alpinus*, *D. neglectus*, *Dodecatheon Meadia*, *Erigeron mucronatus*, *Gentiana Farreri*, *G. sinornata*, *G. verna*, *Geranium Traversii*, *Gemma Borisii*, *Haberlea rhodopensis*, *Helichrysum bellidifolium*, *Hepatica angulosa*, *Hypericum fragilis*, *Iberis Little Gem*, *Levisia Lecana*, *Lithospermum prostratum* Heavenly Blue, *Mertensia primuloides*, *Myosotis rupicola*, *Oxalis emneaphylla*, *Phlox divaricata* Laphami, *P. subulata nivalis*, *P. s. Vivid*, *Potentilla* Miss Willmott, *Primula Cockburniana*, *P. helodoxa*, *P. pubescens alba*, *P. rosea splendens*, *P. sikkimensis*, *Ranondia pyrenaica*, *Racoulia australis*, *Sanguinaria canadensis*, *Saxifraga Burseriana* Gloria, *S. decipiens grandiflora*, *S. longiflora*, *S. oppositifolia*, *Shortia galacifolia*, *Silene Schafta*, *Tunica Saxifraga*, *Verbena chamaedryoides*, *Veronica rupestris* and *Viola gracilis*.—ALBYN.

A FINE COLD-HOUSE PLANT.

IN *Clematis Thunbergii* we have a very useful decorative plant for a cool greenhouse or corridor. It has a very graceful habit, hanging in long vertical streamers from 5 ft. to 8 ft. in length, which produce panicles of sweet-scented creamy white flowers at each node. When a number of these long, graceful

shoots are hanging from the root in flower, they give the effect of a beautiful floral curtain. The plant is usually in flower during September and October. In the Cape flora it is said to be readily recognised from other Cape species by its lanceolate sepals and pointed slightly twisted flower-buds. In cultivation the buds are hardly twisted, but the sepals are slightly. The leaves are described as pubescent, but with us they are glabrous; they are sub-bipinnately parted, pinnae distant, leaflets petiolate, broadly ovate, acuminate, with three or more acute teeth on each side. The panicles are described as shorter than the leaf, but they vary in this respect, for while, perhaps, the majority are shorter, some are considerably longer. The flower-buds are ovate and pointed, the sepals spreading, lanceolate, acuminate, while the filaments are hairy at the base, with linear glabrous anthers, and the stigma (which projects beyond the stamens) is densely covered with silky hairs.

The plant, which is very rarely met with, was introduced to this garden fourteen or fifteen years ago by seeds sent by the late Professor Pearson from South Africa, where this interesting and ornamental species is found in the woods of Adow, Uitenhage. It is, under natural conditions, a rambling climber.—F. G. PRESTON. *Botanic Garden, Cambridge.*

ASTER OCTOBER DAWN.

EITHER the man who wrote the notes on the "Shrubs, Michaelmas Daisies, etc., at Vincent Square," is wrong or I am in our description of the new October Dawn in *THE GARDEN* for October 27. On page 555 it is described as "a tall Novi-Belgii variety," while on page 557 I describe it as a "low-growing plant." I took my height from a very healthy plant in my garden which, measured on October 26, I found to be exactly 2½ ft. high. It would not much matter whether the note-maker's "tall" was the same as my "low,"

for, after all, tall and low are relative terms; but it would be provoking to put October Dawn in a mixed border expecting it to grow up and be as tall as Magnet, Edwin Beckett, King of the Belgians and Louvain, which most certainly it is not. Again, I would hardly call it a thread-petalled variety if it is compared with either Heather Glow, Grey Lady or Miss Eisle, and I would never say that the ray florets recurve at their tips. If they did might it not be either that the poor things in the hall wanted water or that the sprays had been broken off where they joined on to the main stem. One does not think of the difference there is between breaking off or stripping off the little branches of a Michaelmas Daisy close to their junction with the main stem, and cutting or breaking them off at a little

distance from it, until one is face to face with the results. I never did until last week, when I completed the wind's work and finally severed the slender connecting link of two fine sprays of Edwin Beckett from the main stem and, to go with them in a vase, broke off another at a little distance from it. The three were duly put in water. The next day the stripped-off branches had the ray florets of their flowers all reflexed at their tips, while the other was looking "in the pink." Now comes the "proof of the pudding." The distressed branches were taken out of the water and a couple of inches of the bottom part of each stem amputated. They were then returned to their old companion in the vase. The first bulletin was "Patients doing well." The second and last, "The operation has been entirely successful and the patients have quite recovered." It

THE STILL UNCOMMON CLEMATIS THUNBERGII.

is something also to know of the good office a hammer can perform for us when we have to deal with refractory cut flowers. Just nerve yourself to pound with gentle blows about an inch and a half of the end of their stems before putting them into water and note the result. It is a floral example of the old proverb, "Spare the rod and spoil the child."—JOSEPH JACOB.

FORTHCOMING EVENTS.

November 20.—Sevenoaks Gardeners' Chrysanthemum Society's Meeting.

November 22.—Royal Botanic Society's Meeting.—Wargrave and District and Gardeners' Society's Meeting.

ARTIFICIAL FERTILISERS FOR WINTER USE

What Kinds to Use, and Where, When and How to Use Them.

ARTIFICIAL manures is a common term, used, after the manner of many familiar terms, with the confident assumption that the sense in which it is used will be readily understood, and yet, when we come to rock bottom, in the majority of cases but hazily understood by those who either use or hear it. The very practical man may wish to set aside argument by remarking that the term is so well understood that explanation of its meaning is waste of time, those who like to be more voluble will explain that artificials are plant foods other than farmyard or stable manures, while the stickler for accuracy will reply that there can be no such thing as artificial manure because artificial has come to mean imitation, and imitation would be no food for a plant.

In point of accuracy the last man has it, but he has told us nothing more than we knew before, and the first man said as much; we get nearest to the point of utility when we accept the explanation that artificials are plant foods other than farmyard or stable manures, or to make it still further exempt from criticism we will substitute the more general term, animal manures. Let us, then, without further parley state that this article is concerned with plant foods in concentrated form, both chemical and organic in character, and while we make no pretence that we have anything new and remarkable to relate, we will endeavour to tell something in plain language of the virtues of various fertilisers, the soils and crops for which they are suitable, and the time and manner in which they should be applied.

The subject is too large to be exhausted in a single article, or even to be compassed within its scope, and our present intention is to confine ourselves to such fertilisers as may best be used between now and early spring. Even with this limitation the article will be very incomplete, for the subject of soil enrichment and plant feeding knows no finality.

We have, at this season, two sections of the garden to deal with, one being the land that has been vacated by summer season's crops and is to be dug and prepared for further planting, and the other that which is occupied by more or less permanent planting, including fruit and ornamental trees, Roses and hardy perennial plants, and also lawns. We have further to consider the character of the soil and the class of plants either growing or to be grown upon it.

Vacant land may more conveniently be dealt with first, because a considerable part of what we have to say will apply also to occupied land. The terms commonly used to describe garden soil are light, medium and heavy, but such terms are too vague and rough to base a discussion of fertilisers upon. A light soil may be a hungry sand almost destitute of humus, or it may be very largely composed of vegetable matter. A heavy soil may be rich and fertile or it may be a lifeless, sour and unwieldy clay. To treat these varying soils in the same manner would be extravagant and quite wrong; in fact, would in all probability defeat the end in view. To study the mechanical condition of the soil should be the unfailing rule, and in actual practice it seems to me we but rarely find sufficient attention devoted to it.

We have one school which professes to despise all chemical plant foods and maintains that "plenty of muck" is all that any soil requires. As a matter of fact, there are many gardens, especially such as are enclosed by high walls or fences, that are actually manure sick, and that

really require "chemicals" for the explicit purpose of cleansing and purifying the soil. On the other hand, we have "lime cranks" whose one theme is "use plenty of lime." Nobody can have a more wholesome respect for lime than myself, and its value is immense, but it is as easy to do damage with lime as it is to ruin a child's constitution by the haphazard use of purgatives and tonics, which are useful under certain circumstances but positively dangerous in ignorant hands.

Caustic lime on a hungry, sandy soil will simply intensify its poverty by burning up what little humus there may be intermingled with the sand. Chalk, or, in scientific language, calcium carbonate, is the form of lime to use on such soil, for it does not burn, but, on the contrary, will help to cool soils that become too quickly parched, and by holding the particles of sand together the chalk assists in conservation of moisture. Chalk is best applied in a fine, dry, granulated form, and may be spread over the surface of freshly dug soil at the rate of half a hundredweight per square rod. Stone fruits, such as Plums, Cherries, Peaches, etc., must have lime, and the best form for use on light sandy soil is chalk, and the best time to apply it is between October and the end of the year. On stubborn clay soils freshly slaked lime or ground limestone is more suitable than chalk; so is it in the case of old garden soils which are overcharged with humus.

It is quite essential that care shall be exercised in treating land that is abundantly charged with lime. Many gardens on chalk downs have ample lime in the soil, and it is in such cases that superphosphates may be used to greatest advantage. It is well to keep in mind that there are various grades of superphosphates, the lowest grade averaging not more than 25 per cent. of soluble phosphates, whereas concentrated superphosphate made from bone ash or bone charcoal may contain over 40 per cent., and a specially high grade sample known as "double" superphosphate will reach 80 per cent. It is as cheap to use the strongest or highest grade as the others, for a reduced quantity will have the same effect, and where carriage is involved there is a distinct advantage in using that which reduces bulk and weight.

A great deal of superphosphate is used on lawns, sometimes with excellent effect, and sometimes with harmful rather than beneficial results. Superphosphate is not, generally speaking, suitable for peaty or sandy soils, but is very useful on chalky soil and on a fibrous loam of good heart. Its benefit to plants consists in the phosphoric acid it contains, but the best method of treatment is to mix it with sulphate of ammonia, using half the bulk of ammonia to that of superphosphate. Such a mixture is excellent for lawns where there is no deficiency of lime; but, where lime is needed, granulated chalk may be used in conjunction, mixing the whole with finely sifted soil, a good top-dressing consisting of 14lb. of sulphate of ammonia, 28lb. of superphosphate (concentrated), 56lb. of granulated chalk, 1 ton of sifted soil. This quantity suffices for a full-sized tennis lawn. The same mixture of chemicals without the soil may be dug into arable land at the rate of 7lb. per square rod or even up to 10lb. or 12lb.

On the peaty soils, for which superphosphate is unsuitable, basic slag may be used, and it is also useful for very wet and for heavy clay soils. Basic slag will not mix with either ammonia or superphosphate, and is best used alone, the present month and on through December being the best time to apply.

Basic slag is a fertiliser that varies greatly in quality, some samples being so poor that they are almost worthless. Purchasers should insist upon a guaranteed analysis, and should select a sample that contains about 20 per cent. of phosphoric acid, and 12 to 15 per cent. of iron. It must be ground to a fine smooth powder, and when distributed should be raked or hoed into arable land, or if used on grass should be well mixed with sifted soil.

The value of potash is freely commented upon, and in the kitchen garden where root crops are grown it is essential that the soil shall not become deficient in potash. Generally speaking, heavy soils contain sufficient, simply requiring lime to liberate the potash. A good deal of potash may be provided by burning refuse and digging in the ashes, but, where necessary to purchase, it is advisable to take special note of the fact that for light, sandy and dry soils, muriate of potash is the best form to use, while sulphate of potash is more suitable for heavy soils and wet situations. If a good grade of either is purchased, shewing an analysis approximating 50 per cent. purity, a dressing of 4lb. per square rod is ample. These are good fertilisers for Roses, hardy perennials and, in fact, for all kinds of plants.

A cheaper fertiliser containing potash salts to a degree sufficient to be beneficial to standard, half-standard and bush fruit trees, Raspberries, Currants, Gooseberries and Strawberries is kainit. This is an imported chemical used just as secured from mines, and may be used at a rate of 7lb. or 8lb. per square rod. It should be applied if possible before the end of November. Kainit is not of pure enough quality to use for pot plants, the best form of potash for this purpose being nitrate of potash, which should be used in water at the rate of 1 oz. to a 3-gallon can. All kinds of foliage plants will benefit by an occasional application, but variegated plants should not be allowed more than half the quantity given to Palms and other green-foliaged plants.

This is distinctly not the time of year to use either sulphate of ammonia or nitrate of soda by themselves. These are useful tonics, to be used with caution and moderation during the most active period of growth. Bone ash is a fertiliser that is deserving of far greater popularity and more general use than it appears to enjoy at present. It must not be confused with bone meal or bone flour, for it is a product of bones burnt to a white ash, and a pure sample will show a percentage of 75 to 80 per cent. of phosphate of lime. It is particularly valuable on old rich black soil that abounds in humus and suffers from sourness or acidity, and is equally beneficial to trees and to plants of a soft-wooded character.

Of bone meals, guanos and other organic fertilisers too much requires to be written to permit of their inclusion in this article, but with the Editor's permission I will deal with the more important of these in a further article. Broadly speaking, the organic fertilisers are more convenient and suitable for working into the soil between standing plants—such as beds of Roses, herbaceous borders, groups of flowering shrubs and permanent fruit quarters—than the inorganic or so-called chemical fertilisers, and a composite manure made up of a properly balanced blend of fertilisers that will not "fight" is generally useful. There are certain substances that should never be mixed; for instance, superphosphate should not be used in conjunction with either nitrate of soda or basic slag. Lime and sulphate of ammonia will not join hands, nor will basic slag agree with sulphate of ammonia. It should be common knowledge that lime and soot fight each other, and yet it is not uncommon to see or hear the mixture recommended. A. J. MACSELF.

COMPOST-MAKING IN WINTER

With the winter solstice comes a great press of work, and, before that date, ample supplies of various composts should be ready.

THE winter months undoubtedly form the best period of all for the making of compost, as there is generally plenty of time then, not only to secure adequate supplies of the right kind of material, but also to mix this together with the care and thoroughness which is so essential to success.

Most of us do not think of compost-making as a winter job on account of the material not being required for several weeks or perhaps not, indeed, for a couple of months. More often than not the work is forgotten until seed-sowing time comes along, when it is found that one's supply of mixed compost has run out, and then it is a case either of buying ready mixed compost and paying dearly for it over the nurseryman's counter or making up a hurried mixture with such materials as can be got at short notice, in some cases one or other important ingredient having to be omitted on account of its not being available before the mixture has to be made. The results of using hurriedly mixed compost or the so-called "ready-made" mixtures are very often disastrous, and it is far better to get to work in good time and make up some really satisfactory potting soil which is sure always to give good results.

Let us look first of all at the materials which are required for different types of potting soil. For ericaceous plants peat is necessary, and therefore a supply of this should be ordered, its amount varying with the number of these plants which are to be potted on or otherwise cultivated. Generally, peat does not occupy more than about one-third of the total bulk of the potting soil, and it will not therefore be necessary to buy a considerable quantity of the material unless one specialises with such plants almost to the exclusion of anything else.

A supply of old hot-bed manure is an essential ingredient of all potting soils, and arrangements must be made for an adequate quantity of this to be delivered, unless one has on the place an old hot-bed or hot-beds to break up now that their heat has gone. Old hot-bed manure is the mildest form of humus which is available, but is quite distinct from the washed out, dried material which is so often offered as "potting manure." The genuine article is of a dark brown colour, only slightly fibrous in character and, while not actually greasy, is distinctly spongy. In addition to this it should be practically odourless.

Cow-manure is another useful ingredient of potting mixtures, and if one has cows within reasonable distance, a load or two of the fresh manure should be purchased at once and made into as large and as truly conical a stack as possible. It should be left undisturbed for at least twelve months, and better still two years, after which period it will be exceedingly mild in character and fairly rich in valuable plant food.

If, however, cows are not within easy reach, it may be necessary to purchase a supply of this manure, partially or completely rotted, but preference again should be given to that which is not more than a year old, as it is possible, or nearly always possible, to store it under more ideal conditions for retaining the full value of its plant food in the garden than is the case on farms.

The basis of all compost consists largely of loam, and it is essential that a good fibrous variety

be obtained if loam itself has to be purchased. When one has enough loam to carry on with for a few more months, it pays to buy turf instead of loam, and this can generally be done if a sharp look out is kept on land which is to be cut up for new houses. Naturally, it does not pay to purchase lawn turf for making into potting soil, but, on the other hand, it will prove a ruination to the grower if he takes any kind of rough turf which may be offered to him, as this is very often full of the foulest weeds, many with creeping underground stems or roots, and its grassy portion may in addition be charged with dormant seeds which will germinate all too readily if the soil is used for potting greenhouse plants. Turf, therefore, before it is purchased should be inspected, and only that of which the major portion consists of the less vigorous grasses should be used for stacking as potting loam.

It is commonly advised to make turf stacks, placing the turf grass side downwards, but where the loam is required in a few months time a far better plan is to make a stack in sandwich form, placing the turves grass to grass and soil to soil. If this is done it follows that on disturbing the heap the grassy portion is not actually mixed with the rest of the soil. A layer of loam can be removed first, and then a layer of half-rotted grass can be removed separately for ultimate return to the stack after sufficient soil has been obtained, and in practice it will be found that the quality of the loam is just as good at the end of the period of decomposition as if made in the other way, provided, of course, that the compost is thoroughly mixed before use.

Another essential ingredient of potting compost is sand, and the great importance of its being silver sand cannot be too strongly insisted. Other sands have been used, sometimes with good results it is true; moreover, they are very much cheaper than silver sand, but it nevertheless is unwise to use them, and that for several reasons. First, because they are not as a rule nearly as sharp in character as true silver sand, and consequently do not add the character of porosity to the compost which is so essential; and, again, they do not undergo any special process of purification, and in consequence are liable to contain varying quantities of all manner of poisonous chemicals.

Other ingredients of compost include wood ashes from the garden bonfire, a good supply of which can generally be obtained at the present time, but which it is essential to store in a perfectly dry state until required for use on account of the readiness with which the fertilising ingredients may be washed out, and in some cases it will be found useful to add to the compost some roughly ground wood charcoal. Bones form a very valuable addition to compost, especially for Tomatoes and Cucumbers. Half-inch bones can be used, but I prefer to mix them in as bone-meal or bone-flour, as they then become available more readily.

It is almost unnecessary to mention, I think, one other essential ingredient of potting composts, viz., leaf-mould, or leaf-soil as some gardeners call it. Leaf-mould is expensive to buy, but very easy to make at home, provided that one starts well in advance of the actual time when it will be required. A large stack of leaves is very easily made in some convenient corner, and on this should be placed either a good covering of garden soil or, better still, a load or two of manure.

Leaf-mould can be made in as short a time as seven months, but it is far better not to hurry the operation, as the longer the leaves lie tightly packed together and in the rotting stack the better will be the quality of the mould. It is, therefore, a good plan to reserve one part of the garden exclusively for the making of leaf-mould, and as soon as all the leaves have been dropped from the trees, to cover with soil or manure and to leave them alone until next year's leaves actually start falling, when the corner can be turned out. After cutting up into slices and running these through a riddle, the mould is ready for use.

May I conclude with a word about the mixing of potting composts and how they may best be stored?

First of all, assemble the various ingredients on a convenient and firm mixing floor. The first heap should be the loam, of which, generally, the potting medium may consist of one or two thirds. Over this may be scattered equal portions of leaf-soil and hot-bed manure, when the compost is what is called a "third mixture." If two-thirds loam, the remaining one-third can be equally divided between either leaf-soil and old hot-bed manure or leaf-soil, peat and sand. With the one-third mixture sufficient silver sand to render the soil nicely porous must be added afterwards, and one or two potfuls of bone-meal or wood ashes per bushel of soil can also be added subsequently.

The best results are obtained by mixing in each ingredient separately, that is to say, starting with the loam heap, one covers it over with the leaf-soil and then turns it over on to a new piece of the floor thoroughly to mix in the addition. After that the pile is again covered with old hot-bed manure or peat, as the case may be, and then it is again completely turned over on to another piece of floor to ensure complete mixing (generally back into its original position).

When one is mixing in various dry materials in small quantities, such as bone-meal, wood ashes and silver sand, these can all be mixed together in a separate pile first and then the mixture added to the soil mixture in the way above described.

I do not know any other way of working, without the use of a machine mixer, by which one can be sure that all the materials are evenly mixed in throughout the whole, and although many gardeners favour less troublesome ways of mixing, they cannot be said to give satisfactory results. The mere single turning of a combined heap of all the varying materials thrown together anyhow invariably causes uneven results.

A reasonably dry place of storage is absolutely essential in the first instance. I do not mean to imply that I should take a potting compost into a greenhouse and dry it through and through, as it would certainly not give satisfactory results were this to be done, but it is absolutely essential that the material should not be made into a stack in the open air, to be drenched through by winter rains. The ideal place for storing potting soil is a shed the front part of which is open, but if this is not available and the heap has to be made outside, be sure to throw over it some thick boards to cover it completely from drenching rain. Special brands of potting soil for the more fastidious plants can be conveniently stored in barrels during the winter in any shed or outhouse which is reasonably cool. If they have to be stored during the summer, the heap should be made up against a wall and a couple of old doors or frame lights be put over it at an angle to throw off the major part of the rain. It is only by careful attention to storage that the maximum results can be obtained from the use of even the best quality potting composts.

E. T. ELLIS.

Flowers all the Summer

Nothing gives a longer flowering period and lasts so many years without replanting as

CUTBUSH'S Gold Medal DWARF PERPETUAL FLOWERING Polyantha Roses

Constantly in flower from JUNE to NOVEMBER. Make perfect beds and splendid for cutting.

STRONG PLANTS from 12/- per doz.

Ten Thousand Standard Roses from the Cotswolds.

In no part of England does the Wild Rose grow more luxuriantly than on the wind-swept Cotswold Hills, making, during the summer months, every wayside hedge and copse a picture of delicate beauty.

The Standard Roses grown in the Cotswold Nurseries, of all the best and up-to-date varieties, are equally vigorous and, grown on straight stout stems of the English briar and with good heads, are a very different plant to those sometimes sold budded on stocks which will not stand upright without support.

You may not have been satisfied with your Roses in the past, but a trial order of the well known Cotswold Roses will convince you that they are the best procurable.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Seakale.—The forcing of Seakale is an easy matter if well ripened one year old roots are available and space can be found underneath the stage of a greenhouse. Large deep pots are suitable, and five or six crowns placed in each, making the soil fairly firm between the roots. Another pot of the same size should be arranged on the top to exclude light, as perfect darkness is necessary. All crevices and holes in the pots should be filled with damp moss or anything that will keep out the light. Gentle forcing should be practised, and a temperature of 45 to 50 will be ample for a start, the temperature being increased a few weeks hence, but it should never exceed 60° or the growth will be weak. Water should be afforded in sufficient quantities to prevent the soil from becoming dry.

Horseradish.—A quantity of this pungent root may be lifted and stored in ashes until it is needed in the kitchen. This is often badly grown and much neglected. If large roots are needed, an open situation should be chosen and single crowns planted about 12 ins. apart.

Leeks. Where these are growing in trenches the final earthing up should take place, but soil should be kept out of the leaves. We grow a crop on the flat, making the holes with an iron bar, and in such cases no earthing up is required, but the ground should be hoed and kept free from weeds.

Chicory.—This is a useful winter salad, and roots may now be lifted and treated similarly to Seakale. Slugs are partial to the young, tender leaves, and so should be destroyed, or the crop will be spoilt.

The Rock Garden.

General Work.—A well appointed rock garden is of more than ordinary interest, especially if new and rare plants are added occasionally and the more robust kinds not permitted to over-run their smaller brethren. These strong growers should be dealt with as the necessity arises, and during the winter months there will be much to be done in the rock garden. Some of the bays, pockets and fissures will be benefited by fresh soil, and many plants will need top-dressing. Shrubs that have outgrown their stations may be uprooted and replaced with smaller examples, unless they may be pruned sufficiently without destroying their beauty. Strong-growing plants in bogs may be lifted if they are overcrowded, divided, and the best pieces replanted in new soil. Slugs are often troublesome, and if they are not kept in check many plants will be ruined. Wahlenbergias are eagerly sought for by these marauders, and unless the plants are protected with wire gauze circles they are invariably devoured. Slug traps will be found most useful.

The Flower Garden.

Zephyranthes candida.—This is a fine bulbous plant, and the flowers, resembling a white Crocus, are produced in the autumn. Bulbs may be planted from November till March, preferably in a warm, sandy soil and where they need not be disturbed for several years.

Galetia candicans is a handsome plant, suitable for large groups in the flower border, growing to a height of 3 ft. to 5 ft. and bearing white, bell-shaped flowers. The bulbs may be planted from November till the spring, and they will succeed in ordinary garden soil.

Fruits Under Glass.

Vines.—When an opportunity occurs the early viney should be prepared for starting the Vines a few weeks hence whenever circumstances will permit. It is a mistake to begin early unless the necessary fuel be at hand. In the meantime, each spur should be cut back to two eyes and the rods thoroughly cleansed. Use a stiff brush and a fairly strong solution of insecticide, first removing all loose bark, under which will often be found mealy bug. If this pest is present, every effort should be made to eradicate it. A close watch should be kept for mealy bug throughout the year, and whenever one is seen it should be touched with a camel-hair brush dipped in methylated spirit. The house should be washed down, the walls linewashed, and if the joints are bad they should be filled with cement, while it would be an advantage to paint the woodwork of the viney. The surface soil of the border should be removed and replaced with fresh loam

and a moderate sprinkling of Thomson's Vine Manure. When the work is completed the ventilators should be kept open to their fullest extent until it is decided to close them in order gently to start the Vines into growth.

Outside Borders.—These may be covered with moss, or ferns, or leaves and a thin layer of straw litter or bracken which may be kept in position by wire-netting.

Midseason and Late Vines.—When the rods lose their leaves the necessary pruning may be done, and the houses and rods thoroughly cleansed.

The Hardy Fruit Garden.

Apples and Pears.—Both in large and small gardens where Apples and Pears are grown, the types of trees known as pyramid, bush and cordon will usually be found in fairly large numbers. The latter can be bought as single, double and triple cordons, and are useful for planting on walls and arches. There is often a little space on a fence or wall which could be utilised to advantage by filling it with a cordon-trained Apple or Pear. These trained horizontally are also suitable for various positions, such as near the walks of the kitchen garden. These should be pruned on the spur system, each growth being cut back hard at this season excepting any shoots needed for extension, which should be slightly reduced. Bush and pyramid trees which have been carefully trained and are in a bearing condition will not require a lot of pruning, but ample light and air should reach the whole of the trees.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chapstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Savoy.—Considerable damage is often done to Savoy—especially to those intended for late use—by rain and melted snow settling in the axils of the leaves and thus causing rotting. As a preventive of this evil the following treatment is to be commended: Lift the plants of the crop intended for late use and lay them in rather thickly well over on their sides. The effect of this will be that instead of the rain and melted snow lodging in the axils of the leaves, it will run off the plants altogether. Ormskirk is the favourite variety for late use.

Celery.—Frosty spells may occur at any time now, and if such threatens it is a wise plan to lift at least a fortnight's supply and store it among soil or sand indoors, or lay it in thickly out of doors, packing protecting material over it to keep it frost-proof. In such circumstances see that the tops of the entire crop are protected by some littery material, and, in addition, make the sides of the trenches of a part of the crop frost proof so that supplies may not be interrupted should the frosty spell prove of a protracted character.

Leeks.—Should severe frost threaten, a portion of the crop should be treated as advised for Celery.

Fruits Under Glass.

Late Peaches.—The trees will now be completely deholed, and as the Peach takes such a short period of rest, the sooner the trees are pruned the better. First regard should be had to the frame work of the tree. In the case of young, partially developed trees, the main extension shoots should have only the immature points cut away; this will cause a break, thus furnishing additional shoots for filling up the expanding area to be occupied by the tree. In the case of established trees any damaged, gummed or otherwise diseased branches should be cut away and means taken to fill up the blank with healthy young wood. Having seen to the general framework of the tree, the shoots that bore fruit this year should be cut back to the base of the succession shoot which was trained to take the place of the shoot now being discarded. The immature point of the succession shoot should be cut away, making sure that it is cut back to a wood-bud. A wood bud is easily distinguished from a fruit-bud by its being less plump and more elongated. Pruning finished, the tree should not be tied in the meantime, only the main branches being loosely caught to the trellis.

Early Peach-House.—The house should now be cleaned and otherwise put in order preparatory to starting for the ensuing season. Commence by tying the branches loosely in bundles so that tree access may be had to the roof. Thoroughly

wash down all the glass and woodwork, and linewash the walls. Next, paint the trees with Gishurst's Compound, dissolving some clay or heavy loam in the mixture so that the dressing will more readily adhere to the branches and shoots; then tie and train the tree branches and shoots—into the correct position. Remove a few inches of the surface of the border and, having pricked the border over with a fork, replace the removed soil with fibrous loam plus a moderate dressing of bone-meal or steamed bone-flour, adding a light dressing of ground lime, and finish by giving the border a moderate watering.

The Flower Garden.

Cuttings in Frames. A sharp look-out should be kept on cuttings of Pentstemon, Pansies, Violas, Phloxes, etc., in frames, first to see that damping does not occur through insufficient ventilation, and, again, to see they do not suffer from lack of water, also to see that mice do not work mischief, which they are apt to do if not sets in and the frames have to be matted up for a time.

Gladioli.—Corms which have become fully ripe should now be cleaned and stored away in a drawer or other dry, cool, but frostproof place.

Roses.—In cold frosty districts some dry earth should be drawn up and around the stems of the Teas and Hybrid Teas; this ensures that at least one or two buds will be safe, although considerable damage may be done to the upper part of the bush. Where a bed or other area is occupied entirely by Teas, it is a good plan, should severe frost threaten, to scatter some bracken or straw among the bushes. The planting of Roses should be completed as soon as possible now, as growth will soon be practically at a standstill.

Hedges.—Any deciduous hedges, such as Thorn, Beech, Common Privet and Cotoneaster Smonsii about the grounds should now be pruned, the hedgebill being the most suitable tool for pruning this class of hedge.

General Work.—On wet, stormy days many jobs may be carried through comfortably indoors. These include the cleaning, grading, tying and storing of stakes, the making of good-sized labels for the bigger herbaceous plants, and if on a fine day a note of such requiring renewal is taken, the writing of the labels may also be undertaken. Propagating boxes may also be made or repaired.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Chrysanthemums.—As the earlier-flowering varieties pass out of flower they should be cut down and some of the best plants retained for stock. They are best stood in a cold frame, where they will get plenty of light and ample ventilation. Late-flowering varieties should be given plenty of standing room and kept as cool as possible.

Clivias which have been kept in a perfectly cool house and somewhat dry at the root will now respond to a little heat; thus, if a succession is required, a portion of the stock may be introduced to a warm house. At the same time some of the surface soil should be removed and replaced with a top-dressing of rich compost. Clivias make an excellent permanent feature in the conservatory, where they may be planted out in beds or borders.

Azaleas of the indica section generally should be kept perfectly cool at this time. Where they are required, however, to flower for early work some of the early-flowering varieties should be selected and introduced to a warm house, starting them in a temperature of about 55°. They should be kept well syringed during bright weather, as dry atmospheric conditions may induce an attack of thrip.

Cyclamens.—The earliest batch of plants that have well filled their flowering pots with roots should be assisted with weak applications of soot water or a little guano. There is a mistaken idea that Cyclamens should not be given manure in any form, whereas they, in common with most plants, readily respond to judicious feeding. They should be kept well up to the roof glass and a moist atmosphere maintained. Although August is the best time for sowing Cyclamen seed, no one need be deterred from sowing at this time, as quite good plants may be obtained from such a late sowing. Young plants raised from seed sown during August should be stood on a shelf well up to the roof glass in a house with an intermediate temperature, affording them water very carefully during the dull days of winter.

Nandina domestica. This beautiful evergreen shrub is very hardy in the South, although it does well in sheltered positions in Devon and Cornwall. It is, however, an ideal plant for a cool conservatory, especially where it can be planted on a well drained bed or border, as it is not so good at its best under pot cultivation. It is best grown in a compost consisting of light leaf-mould and peat, and may be propagated by means of the more slender half-ripened shoots, standing the cutting pots under a bell glass in a cool greenhouse. It is such plants as this that are on the border-line of hardiness that should be more considered for the furnishing of large

cool or even unheated conservatories, for in such house an interesting collection of plants may be grown at little expense.

Buddleia auriculata. This South African species cannot be considered hardy, although it is now flowering freely outdoors in a recess of the temperate house at Kew. Although it is not a showy plant, its brownish flowers are produced in great profusion. It is, however, so sweetly scented that for this alone it is worth growing a few plants for the cool conservatory. It is easily propagated by means of cuttings, selecting the small twiggy side shoots for this purpose.

Royal Botanic Gardens, Kew.

J. COULTS.

BIRMINGHAM CHRYSANTHEMUM SHOW

THIS was the fifty-ninth season of the Show, and the floral exhibits were better than last year, the group and cut-bloom sections showing a decided advance. The fruit classes, however, were not so well filled as last season, for reasons well known to all of us, but what was lacking in quantity was made up in colour and size. The miscellaneous and non-competitive exhibits were, as usual, very numerous and attractive. The vegetable classes were well contested, showing good culture, though to our mind all the specimens were on the "overlarge" side, lacking quality and involving much waste in use. Potatoes were shown in perfect condition, but in too many, far too many, varieties—those standing out prominently being King Edward, Arran Comrade, Arran Chief and Kerr's Pink.

To come back to the Chrysanthemums, Class 1, for thirty-six Japanese blooms, brought only one exhibit; but the flowers were fresh, well coloured and of immense size. The best blooms were Maestrie, Major Wheatley, Rose Day, Queen Mary, Golden Champion, H. E. Converse, Mrs. Rupert Wilkes, Mrs. Algernon Davis, Helmath, Prince Albert and Mrs. George Moore. Mr. H. Woolman was the exhibitor.

In Class 2, for a collection of Chrysanthemums with Ferns and foliage plants, the first prize was awarded to Sir George Kendrick, who had furnished the front of the group very well. Mr. W. H. Cadbury was placed second with a very meritorious exhibit, and Mr. J. Kendrick third.

In Class 3 Mr. Woolman was again to the fore, his group of singles being certainly one of the finest ever staged. Phyllis Cooper (yellow), Portia (red), Bronze Mollie, Mrs. F. Hancock and Langleine were some of the more noteworthy varieties.

The principal prizewinners in the cut bloom section were the Dowager Lady Annaly, Mr. H. Woolman, Mr. W. Gresson, Mr. Keop, and Mr. Robinson.

The dinner-table decorations brought over a dozen contestants, the first prize being awarded to an autumn-tint combination of colours—bronze, crimson, yellow and green. This was arranged by Mrs. H. W. Shipton, and was very effective.

Worthy of note were the first prize twelve Begonia Gloire de l'Oranie in 6-in. pots, many of the plants measuring over 4 ft. across. They were all covered with nice fresh blossom. These were exhibited by Mr. L. Spiers of Edgbaston. A group of *Silene*s brightened up its immediate surroundings, the scarlet blossoms shewing to great effect under subdued light.

The principal prizewinners in the fruit classes were Captain Heales, Foxley, Hereford; Mr. C. Powell, Warburton Hereford; the Marquis of Exeter; Mr. Hugh Andrews, Winchester; Gloucester line; and Captain Drummond, of

Southampton, the last named excelling in all his entries. Mr. Powell exhibited fine dishes of Cox's Orange Pippin, Lane's Prince Albert, Charles Ross and Allington Pippin. Collections of fruit were staged by two exhibitors, viz., Mr. Toolley and Mr. L. Smith, the latter being awarded the premier honour with a very fine collection of Apples, Pears, Grapes, Plums, Nuts, etc.

Mr. H. Woolman staged a handsome group of cut Chrysanthemums; Messrs. J. House and Son shewed their fine forms of *Scabiosa caucasica*; Messrs. E. Webb and Sons (Stourbridge), Limited, a useful collection of vegetables; Mr. Ellison, West Bromwich, Onions and Ferns; and Messrs. Baker, Wolverhampton, shrubs and conifers.

Messrs. J. Waterer, Son and Crisp arranged a group of choice horned plants, flowering shrubs and conifers. Standard and weeping Hollies were conspicuous here; so were many of the great genus *Berberis*, such as BB. aggregata, brevipaniculata and Gagnepainii, also *Cotoneasters* in variety.

Messrs. W. J. Godfrey and Sons staged an effective group of single-flowering Chrysanthemums, obtaining an award of merit for Mrs. T. Hancock (light salmon colour), Rayleigh (deep crimson), Godfrey's Gem and Gorgeous.

Messrs. Daniel Brothers had a collection of Apples, including several new varieties; Messrs. Hopwood of Cheltenham staged a collection of hardy fruits in many varieties.

OBITUARY

MR. HERBERT JONES.

Just as we are going to press we hear with much regret of the death at a comparatively early age of Mr. Herbert Jones, until recently proprietor of the Horsecombe Quarries, Bath, so well known for their stone vases, ornaments, garden houses and such like. Mr. Jones, whose health had for some time given cause for anxiety, passed away on November 3 at Weston-super-Mare. Mr. Jones was a familiar figure to visitors to the great spring shows in the grounds of Chelsea Hospital, where year by year he set up a varied, but always interesting and beautiful gardens.

CONSTANCE TYHURST DAVIS.

READERS of THE GARDEN, especially old readers, will share our regret at learning of the death of our old and valued contributor "Anne Amateur," which took place on Tuesday, November 6, in the Ashdown Forest, whither Miss Davis had repaired for her health's sake. Miss Davis was strongly opposed to very large vegetables as seen on the exhibition table, and many times took up her pen to advocate a saner standard for the exhibition table. Though she seemed glad to enter the arena of controversy, she never descended to personalities. Miss Davis

was the author of a number of useful booklets on home brewed wines, sauces, preserves, etc., and was an acknowledged authority on wholesome English cookery. Her remains were cremated on November 8 at Golders Green Crematorium.

BOOKS

"Lawns, Links and Sportsfields."—Mr. MacDonald's book* will be of immense value to all amateur and to most professional gardeners. The general treatment of the formation and upkeep of lawns, etc., is excellent. There are many professional gardeners who are expert in the production of fruit, flowers and vegetables to whom turf is a closed book. They know it has to be mown, they generally over-rol, but its scientific treatment is to them unknown. In this book the reader has all the information necessary for the making of a good lawn, croquet ground or tennis court. The instructions as to levelling are excellent. So also are those concerned with drainage, which is perhaps the most important factor in the production of good turf. Mr. MacDonald is evidently a firm believer in artificial as against horse manure. It is, however, open to question whether, when preparing a seed-bed, the latter does not give the best help to young grass plants. This is a much debated point, but where turf for golf fairway and putting greens is concerned the use of horse manure in the top compost is almost universal. Speaking of the time for sowing seed the author says: "There is really no fixed season that can be labelled 'the best' for sowing grass seed." This is a statement to which numbers of experts will take exception. It is held by many that the month of August is the month. For the South of England, the last week of that month; for the North, almost any time. Sowing in the spring is a pure gamble. Where a small lawn is concerned, one can chance it and hope for the best; but for a golf course, where the seed bill can run into £1,500, no sane person would risk a spring sowing. Of course, seed can be sown all through September, but the best results are from an August one. The author deals soundly with turfing, but does not impress upon the uninitiated with sufficient stress the numerous advantages of seeding as against turfing. It is true that turfing is as old as the hills and that seeding is quite a new method of turf production; but it is far ahead in every way. Even in point of time it can hold its own, and if sufficient seed is sown in August it is possible to play tennis on the turf in the following May. "Sufficient seed" should be, for putting greens, tennis courts and bowling greens, at the rate of not less than 20 bushels to the acre; for lawns 8 to 12 bushels, according to the richness of the soil. Seeding is also slightly cheaper than turfing. On the other hand, turfing can be carried on right up to December. When dealing with lawn pests the author is hardly strong enough on the absolute necessity of eliminating worms from all turf. This should be regarded as a *sine qua non*. Where one has a fine bit of turf there is one rule which should on no account be broken, viz., "Snow must never be brushed off." On the question of watering grass the author will again find himself in a minority if he consults the golf greenkeepers. The almost unanimous opinion is that for most parts of England it is an absolute essential. Of course, it must be put on under pressure from sprinklers; further, the supply must not be cut off in times of drought. Above are a few criticisms of what is an excellent little book, which will be most valuable to all who are interested in turf. W. H. F.

NEW SPRAYING MACHINES LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete
without a Sprayer, in fact a Sprayer
is absolutely essential to obtain
best results.

During the War we
supplied a considerable
number of our well
known Four Oaks
Knapsack Sprayers—
Rubber Diaphragm
type—to the Govern-
ment, and we have just
re-purchased a small
quantity back again,
which have never
been used. They are

made of copper but painted Service grey colour.
They have various special additions to the
ordinary machines, and the price to-day would
be £5 each. We guarantee them to be in
perfect working order as new. We will send
one machine carefully packed, carriage paid,
on receipt of 50/-, but cash must accompany
all orders. We would supply 2 machines
for 90/-, carriage paid.

Please mention this Paper when ordering.

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

Cash Prices (including bags): Small (about 1 bushel), 3/-; Large (about 4 bushels), 7/-; 5 Large, 33/9; 10 Large, 65/-; 20 Large, 120/-.

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles, or part beyond.

WAKELEY BROS. & CO., Ltd., 75a, Bankside, London, S.E.1

THE KNOT GRASSES

THE genus *Polygonum* (Knot Grass) is a large one, comprising about 150 species, spread over the Northern temperate and Arctic regions, and extending into the Tropics. Of these, however, only a comparatively small number are worth a place in the garden. Some of the stronger and more robust species, like *P. cuspidatum* and *P. sachalinense* are handsome foliage plants, suitable for woodland, wild garden or waterside, where they can have full scope for their rambling habits. Others, like *P. affine* and *P. vacinifolium*, are valuable plants for the rock garden where there are large spaces to cover. Quite opposite in character to the foregoing kinds, which are all of rambling growth, is the choice Himalayan species, *P. spharostachyum*. This is of tufted habit, with small leaves and spikes of deep red flowers. Of the annual species the best is *P. orientale*, a handsome plant with drooping racemes of rosy red to white flowers. It is well worth a prominent place in the herbaceous border. One of the most valuable hardy woody climbers is the handsome *P. baldschuanicum* from Bokhara, with its twining stems and large trusses of white to pink flowers. When well established, it soon takes possession of good sized trees. The best herbaceous kinds are:—

P. AFFINE (syn. *P. Brunonis*).—This handsome, well known creeping plant comes from the Himalaya. It is a rapid grower and soon forms a wide carpet of matted stems and leaves, studded in the summer and autumn with dense spikes of rosy red flowers about 2 ins. long. It is especially valuable for covering banks and ledges in the rock garden with its evergreen foliage, which assumes a rich colouring in the autumn.

P. ALPINUM.—This most variable species is a native of the Alps of Europe, but forms of it are also found in Northern Asia. It is one of the most handsome of the medium-sized *Polygonums* and might be used more often in herbaceous borders. It grows to a height of 3 ft. to 4 ft., and has a free branching habit, each branchlet being terminated by a graceful plume of spirra-like white flowers in July and August. *P. Laxmanni* is a

smaller-growing form of this species from Siberia and has the rambling habit.

P. AMPLEXICAULE.—Though attractive on account of its spikes of rose-red flowers, some 3 ins. long, this is somewhat coarse in habit and only suitable for the larger herbaceous border. It comes from the Himalaya and forms a strong, woody rootstock, from which spring many stems about 3 ft. high, clothed with clasping leaves. The flowers are produced freely throughout the summer months. *P. a. var. oxyphyllum* is a form of this, with spikes of white flowers about 6 ins. long.

P. CAMPANULATUM.—Another Himalayan species,

this forms a bushy, compact plant from 2 ft. to 3 ft. high, with much branched stems, terminating in cymes of pink flowers in September and October. The upper surface of the leaves is green, while the underside is covered with a brown tomentum. It is quite hardy, but direct sunshine causes scorching, so that it should be planted in a rather shady position. It is a recent introduction, flowering for the first time in this country about twelve years ago.

P. CAPITATA.—A pretty little creeping annual, with numerous rounded heads of pink flowers and leaves marked with dark V-shaped bands. It flowers during the autumn till cut down by frost. From the Himalaya.

P. COMPACTUM.—This is considered by some authorities to be only a form of *P. cuspidatum*. It is, however, of very compact habit, growing only 2 ft. high in poor soil. The plant bears erect panicles of white flowers, instead of drooping ones as in *P. cuspidatum*. It is effective for an isolated bed, but in the border is certain to be troublesome on account of its rambling habit. It flowers from July to September and is a native of Japan.

P. CUSPIDATUM (syn. *P. Sieboldi*).—This is a tall-growing species, also from Japan, with leafy bamboo-like stems up to 8 ft. of more high. Grown as an isolated group in the woodland it is very handsome, with its arching stems and drooping panicles of creamy white flowers. It is a rapid and spreading grower, and must be kept out of the border, as once established it is exceedingly difficult to eradicate.

P. CYMOSUM.—Also known as *Tragopyrum cymosum*, this plant has tall stems up to 8 ft. high, clothed with triangular leaves, and bears cymes of pure white flowers in September and October. It is a native of the Himalaya, and is not of a spreading habit.

P. EQUISETIFORME.—A charming late-flowering plant, with stems like an *Equisetum*, and very small leaves; the species is of bushy habit, up to 2 ft. high, with branching stems and long sprays of pure white flowers in August and September. It likes a warm, dry position, and makes an excellent wall plant. It comes from the Mediterranean region, where it grows in dry, rocky situations.

POLYGONUM CAMPANULATUM, A GOOD PLANT FOR A SHADY POSITION.

P. chinensis.—This is a perennial herbaceous plant, with a creeping habit, and is described as being a native of the Philippines. The leaves are ovate, with a serrated margin, and are covered with a dense, silky tomentum, giving the plant a silvery appearance. The flowers are small, white, and are borne in dense, terminal spikes. It is a desirable species, but rare in cultivation.

P. longimanum.—This handsome foliage plant is common in gardens for some thirty years, and is a perennial, but being only half hardy, the leaves are usually killed during the winter. However, it is easily raised from seeds sown in heat in the spring, and the plants will be ready for planting out in June. It grows about 2 ft. high, with branching stems, clothed with leaves that are covered with a dense, silky tomentum, giving the plant a silvery appearance. It is excellent for the sub-tropical garden or mixed border. A native of the Tropics.

P. rhomboides.—A recent introduction from Western China, this is a handsome plant which grows about 2 ft. high. It is of bushy habit, with soft, hairy leaves and large panicles of pure white flowers in August and September. It is in the way of *P. molle* and *P. rade* from the Himalaya, but is not so tall, and has larger sprays of pure white flowers.

P. orientale (Garden Persicaria).—This is a very old garden plant, having been in cultivation since the year 1707. Like *P. longimanum* it is best treated as a tender annual. If seedlings are raised indoors in heat they will come into flower earlier than those raised outside. A rapid grower, it forms large bushy plants 5 ft. to 6 ft. high, and sometimes, in rich soil, 10 ft. high. The deep rose purple flowers are borne in pendulous spikes on the tips of the branches during the late summer and autumn. It is a useful border plant, of which there is also a white-flowered variety. It is spread over the Tropics of the Old World.

P. polystachyum.—This Himalayan plant is one of the most effective and useful members of the genus. Being of non-spreading habit, it may be used in the herbaceous border without danger of its encroaching on other plants. It is of bushy habit, with branching stems about 5 ft. high. In the late autumn, these stems bear large panicles of pure white flowers which often last till cut down by frost. The flowers are useful for cutting for indoor decoration. It thrives in any light, dry soil, and is valuable for the wild garden.

P. sachalinense.—From the Island of Sachalin this may be described as a larger-leaved *P. cuspidatum*, its leaves being up to 1 ft. long and nearly as broad. The stems reach a height of from 10 ft. to 12 ft. in moist, rich soil, and bear axillary racemes of greenish white flowers. It is a strong grower, of climbing habit and is often used as a fodder plant.

P. sphenostachyum.—A dwarf, tufted perennial from the Himalaya, with narrow, dark green leaves and spikes of deep red flowers from June to September; it is a choice alpine plant and should have a half shady position in moist, loamy soil. There is a variety of this, with more capitate heads of pink flowers.

P. viviparum is one of the prettiest and earliest flowering of rockery plants and one of the most hardy, as well as easy to grow. It forms dense mats of interlacing stems with bright green leaves, covered from July to October, with numerous slender spikes of bright rose pink flowers. In the autumn this plant often becomes tinted with red on the stems and leaves, and is evergreen, making it a most attractive choice for a rockery. It is a Himalayan species.

P. viviparum Alpine Pasture. This is a dwarf plant with spikes of pure white flowers, and is common on the Tibetan Alps.

THE NON-SPREADING POLYGONUM POLYSTACHYUM.

SINGULAR BUT BEAUTIFUL, POLYGONUM EQUISETIFORME.

POLYGONUM COMPACTUM.—RAMPANT BUT EFFECTIVE.

All the perennial species are easily increased by means of division in the autumn or spring, and many kinds are readily raised from seeds sown in

spring. They are all easy to grow in ordinary garden soil, but many prefer a half shady position to protect them from the sun. W. L.

PATH PLANTS FOR WOODLAND GARDENS

WHEN it is one's desire to preserve, as far as possible, a natural effect in the woodland garden, the question as to the best treatment for the paths demands some attention. There are woodland walks, of course, so perfect in their own way that to attempt to improve upon them to any drastic extent would be desecration. For what can be more delightful than a shady track carpeted with mosses, with here and there a tuft of small Ferns, Wood Sorrel, Foxgloves, Snowdrops and the like? But in less shady places one has to face rather a different proposition. The plants mentioned may be delightful for a while, but sooner or later grass will overtake the wild Violets, dwarf Hypericums, Bedstraws, Potentils, and the many other pretty and inoffensive little things which furnish such walks when newly made. Grass means cutting, and while the effect of this may be well enough under some circumstances, it is not so in all, and turf involves constant labour. Heather (*Calluna*) makes a serviceable and attractive path in localities where it does well, but this again needs shearing or mowing and in wet weather is not less objectionable than turf.

The gravel walk may resist the growth of weeds and so save labour, but paths of this kind can be even more out of harmony with the natural features of a woodland garden than is a sward of carefully cropped turf, which, as often as not, is a very shabby makeshift where there is much shade. Still, there is much to be said for gravel in some form, and with the dual object in view of having a dry walk and yet saving labour we have made a kind of compromise in the matter. That is to say, we have, as far as possible, "metalled" the tread of the paths with coarse local grit of a shaly nature, and covered the margins on either side with creeping plants that are robust enough to resist weeds. Moreover, these plants not only eventually save work with hoe and rake, but, if carefully chosen, they bring with them their own charm and interest.

Soil and climate will, naturally, influence one's selection of carpeting plants for paths, but there is a wide variety of inexpensive kinds which will thrive in most places and "do their job" with a minimum of attention.

Taking the shady or half-shady path first, we have the Lesser Periwinkle (*Vinca minor*) in many varieties. These grow quickly and are first-rate for covering wide spaces, whether on the flat or in the form of banks. *Saxifraga umbrosa* and *S. Geum* in various forms are also admirable for such spots. *S. u. primuloides* is especially delightful, making a closely set mat of neat little dark green rosettes which may be left without attention for years. The *Cotulas* (including *Leptinella*) can also strongly be recommended for this purpose, being good doers almost anywhere, while their prostrate, overlapping foliage is distinct and pretty.

Then there are the several *Herniarias*, close carpeters and willing in practically any conditions, nor can one omit to mention the value of *Helxine Solierolii* for our purpose here. If a pest in some places, the very quality which renders this plant noxious in the rock garden is just what we need along the woodland path. *H. Solierolii* is a

speedy grower, soon covering any shady or sunny area of cool soil with its clinging sheet of shiny lettuce green, and even if this little Corsican is not hardy enough for all places, the few bits that generally manage to survive (especially among stones) will ramp away on the return of spring with a determination to make good the loss.

Arenaria balearica is also singularly well adapted for such conditions, and where it thrives few things can be more charming. Though less able to take care of itself in all places, there are occasions when that minutest of all carpeters, the fragrant

A HALF-WILD PATH.

Mentha Requienii, will swarm in a film of green over large areas, reappearing from seed even when destroyed by frost and wet. In half-shade and fairly good soil *Hutchinsia alpina* will be delightful at any season, and under similar or any other conditions the Creeping Jenny, *Lysimachia Nummularia* (the large-flowered form) will not be found wanting.

Linaria aquitriloba is yet another little carpeter of the highest value for our purpose here, nor is *L. Cymbalaria* to be discarded, for its ramping nature is precisely what one wants in any safe place which needs a willing and vigorous carpeter. *LL. hepaticifolia* and *pallida* (both the violet and white) are also first-rate colonisers that will take care of themselves and soon make a beautiful mat of glossy foliage which will be studded with colour nearly all summer.

Tiarella cordifolia is a fascinating little woodlander too good and useful to be omitted from any such list as this, and no less can be said of *Omphalodes verna*, *Sibthorpia europæa*, *Epilobium glabellum* and *nummularifolium* (a pest anywhere else), *Oxalis Acetosella*, *Anemone nemorosa* in

many varieties, *A. trifolia* and the *Pratiens* are a few more suggestions for cool, more or less shady, woodland paths.

While there are few of the above which will not appreciate what share of the sun open woodland affords, the drier, more exposed paths may be margined with such sun lovers as the creeping Thymes, some forms of which are vigorous carpeters in congenial quarters. *Helichrysum bellidoides* is a pretty thing that will also very quickly usurp the place of weeds, and the trailing *H. trimerva* should be given a place. Admirable as they are for our purpose here, one hesitates in recommending the *Accebas*, since their ripe burrs are attracted by one's clothing as by a magnet. Still, one can hardly forego them on that account, and among the prettiest and perhaps the least "burry" are *AA. Buchananii* and *inermis*. These, like the rest of them, are rapid growers, quickly covering the ground with a dense mass of foliage that is attractive at any season. Moreover, they enjoy that blessed quality which every good path

plant ought to possess—they do not mind being trodden on.

Where Thymes do well one may grow masses of *Hypericum Coris* (from seed) and the trailing, moss green *H. repens*. *Globularia cordifolia* and others will also come to mind as ideal for the margins of a sunny path, as will various creeping *Potentillas*, some of which are too rampant for choicer spots. Then there are the *Waldsteinias* in two or three kinds, and some of the lesser *Campanulas* and *Veronicas* will not be out of place or difficult to establish.

Dianthus deltoideus, grown from seed, has made belts of green along some of our paths and, if flowers are comparatively few, the foliage proves a most effectual weed-choker. Any of the more vigorous of the trailing *Phloxes*, more especially those of the *Stellaria* set, which do not look out of place in such circumstances, may be recommended. Then there is that pretty pest *Crucianella stylosa*, which, put to such use as is here suggested, becomes transformed from a rank and irrepressible intruder to a beautiful and respectable member of society. And so one might continue into the region of

lowly, creeping Trefolds to *Lippia repens*, the Bogles (*Ajuga*), the *Hieraciums* and many more. Such prostrate shrubs as the common Ivy in several forms, *Cotoneaster adpressa* and *Polygonum vacinifolium* might be added to the list. *Euonymus chinensis* must not be forgotten, nor can one overlook the charms and adaptability of *Gaultheria trichophylla*, of some of the *Vacciniums* and other creeping ericaceous shrublets

for the purpose under discussion. Enough has, I think, been said, however, in the above paragraphs as to the manifold possibilities offered in the directions indicated. In a matter of this kind one can, for obvious reasons, merely relate personal experience and throw out suggestions. It is for each whom it may concern to adopt, discard or modify as his individual circumstances decide.

N. Wales.

A. T. J.

SOME ERICACEOUS SHRUBS

MOST catalogues of trees and shrubs, when they have given lists and prices of *Rhododendrons*, including *Azaleas*, and Hardy *Heaths*, follow on with a list of "Other American, Ericaceous and Peat-Loving Plants." Such a section contains numbers of very interesting and numerous attractive hardy shrubs. Generally, these plants thrive best in positions shaded, rather than otherwise, from the mid-day sun, though the most desirable cultural conditions are a cool and moist soil, which must not, however, be stagnant and water-logged. Though still termed peat-loving plants, most, if not all the shrubs in such a list will thrive in a loamy soil, to which plenty of leaf-mould has been added; the essential point in the soil composition is that it must contain very little, if any, lime. The positions to avoid are those where the soil is dry and sun-baked.

In common with *Heaths* and *Rhododendrons*, these shrubs do not root deeply into the ground. They form masses of small fibrous roots, or if thick roots are developed these trail near the surface, developing growth buds and stems and thus providing a ready means of increase. Plants prone to such root growth invariably revel in plenty of surface mulching, which at one and the same time conserves moisture and provides plant food. These closely knit masses of roots also tend to make it easy to transplant the shrubs successfully.

ANDROMEDA POLIFOLIA.—In nurseries a dozen or more ericaceous shrubs are frequently included in the genus *Andromeda*. They differ so much in character that it is not surprising that most botanists make at least six, and some more, genera, these including *Cassandra*, *Cassiope*, *Lyonia*, *Leucothoe*, *Oxydendron*, *Pieris* and *Zenobia*. The type plant of the genus is *A. polifolia* of Linnaeus, the Bog Rosemary of Northern Europe (including Britain) and North America. It is a dwarf evergreen shrub, 1 ft. or more in height, with narrow dark green leaves and pink blossoms, at their best during May. The Bog Rosemary is a variable plant in leaf, hence it is not surprising that growers have given varietal names to three of the most distinct forms: *var. angustifolia*, major and *rosmarinifolia*. The *Andromeda* is readily raised from seeds, though to keep them true to name the varieties should be propagated by division of the clumps.

CASSANDRA CALYCULATA.—This evergreen shrub is best known as a native of North America, though it is distributed over the Northern Hemisphere, being found in North Europe and North Asia. It is a bush 2 ft. to 4 ft. or more in height, bearing in March and April dainty small white blossoms. The variety *nana*, as the name suggests, is a dwarf form about 1 ft. high, of compact growth and excellent for an edging to a border or large bed of ericaceous shrubs. In North America, from

THE PENDULOUS RACEMES OF *PIERIS JAPONICA*.

whence the shrub was first introduced in 1748, it is known as the Leather Leaf. Propagation is by seeds, division and cuttings.

CASSIOPE.—This genus comprises about a dozen low-growing alpine shrubs somewhat heath-like in character. The four species brought under notice here are sometimes met with in choice collections of alpinists, none being commonly cultivated. Being natives of Northern regions, the plants require cool and moist conditions. They are, for that reason, better suited to Scottish gardens, though, in the South, damp positions with a northern

exposure may be tried. It is when we get a long spell of drought similar to that of the year 1921 that such moisture-loving plants disappear. A mulching of sphagnum moss and pebbles is very helpful in conserving moisture at the roots. Layering is the best means of increase.

C. TELRAGONA is the best known species. It is a native of Lapland and North America. Growing from 5 ins. or 6 ins. to 9 ins. high the dainty little white bell-shaped flowers open during April. *C. fastigiata*, the Himalayan Heather, is the most showy species. It is a dwarf tufted evergreen growing up to about 6 ins. high, with white bell-shaped blossoms. The flowering season is April and May. *C. hypnoides* from Lapland and North America is a spreading, moss-like plant with solitary drooping white flowers on stalks 3 in. to 4 in. long. *C. Mertensiana*, a native of California and the Pacific coast, is rather upright in growth, averaging 6 ins. to 9 ins. high, with white solitary flowers produced from the axils of the leaves during April.

ENKIANTHUS.—This is a small genus of deciduous shrubs, or small trees, peculiar to Eastern Asia.

The best known species is *E. campanulatus*, a native of Northern Japan. It was first introduced by the late Charles Maries in 1889 when collecting on behalf of Messrs. Veitch. Our tallest plants are about 6 ft. high at present, but Mr. Wilson describes it as a small tree 18 ft. to 30 ft. high. The branches are in whorls, the leaves in clusters at the ends of the twigs, and the flowers very freely borne in racemes during May. They are small and bell-shaped, pendulous, cream-coloured, more or less veined and flushed with chocolate red. This *Enkianthus* is worthy of cultivation for the richness and brilliancy of the autumn tints, varying from rich yellow and fiery red to glowing crimson.

E. japonicus, as the name suggests, is also from Japan. It is a deciduous bush from 4 ft. to 6 ft. high, with nodding white blossoms in April and May. *E. himalaicus* is a large shrub or small tree, introduced first from the Himalayas. Mr. Wilson also found this species in Western China. He describes it as producing a wealth of flowers in June, yellowish-salmon to orange-red with red veins, and wondrous autumnal tints. *E. Meisteria*, better known in gardens as *E. cernuus*, is a dainty deciduous shrub with pretty white fringed blossoms in May. It is a native of Japan.

The species of *Enkianthus* are easily raised from seeds.

Cuttings made of the half-ripe shoots root in a propagating frame with slight bottom heat in late summer. Layering is also practised, the growths bending down readily for the purpose. If the roots are well supplied with moisture the plants thrive best in sunny positions.

OXYDENDRON ARBOREUM.—The Sorrel Tree of the South-eastern United States is one of the few hardy trees flowering during August and September. It carries a cluster of racemes at the end of each branch, the flowers being white. The *Oxydendron* is a deciduous tree, the leaves in autumn turning to

a brilliant red before falling. The best known specimens of *Oxydendron arboreum* in Britain are in Mr. Anthony Waterer's nursery at Knapp Hill, near Woking, being from 25ft. to 30ft. high. The name *Andromeda arborea* is frequently used.

PIERIS.—Under the name of *Andromeda* or *Pieris* we cultivate extensively two most valuable hardy evergreen shrubs, *P. floribunda*, with upright panicles of flowers, and *P. japonica*, with the flowers in pendulous racemes. The flowers of both are white, the inflorescences form in autumn, and gradually developing, the blooms are at their best during March and April. Under happy conditions they grow into large bushes. *P. japonica* from Japan being eventually the taller, though it is not quite so hardy as *P. floribunda*, which is a native of the South-eastern United States. The tallest member of the genus is *P. formosa*, a large evergreen shrub, or small tree, from the Himalayas, with clustered panicles of white blossoms.

In Cornwall, at Pentillie Castle, the height of a large bush, illustrated in THE GARDEN on September 29, 1917, was stated to be 25ft. It is more a shrub for Southern and Western gardens, for even as far north as London it requires shelter. It does well in the Himalayan House at Kew and in tubs for the unheated greenhouse is deserving of attention.

P. taiwanensis is of recent introduction. Mr. Wilson collected seeds during his visit to Formosa in 1918. Those who visited the shows of the Royal Horticultural Society at Vincent Square will remember the beautiful plants growing in pots exhibited in the spring of 1922 and 1923 by the Marquis of Headfort. An evergreen shrub, the pure white pitcher-shaped flowers are borne well above the foliage in a terminal cluster of racemes.

P. mariana is a deciduous species from the Eastern United States. In contrast to the last two species this *Pieris* is very hardy, as our friends at the Arnold Arboretum describe it as one of the most beautiful hardy ericaceous shrubs they grow. The nodding white blossoms are borne in June on ripened wood of the previous season's growth. As it does not, in this country, flower with any degree of profusion and regularity, the desirable condition seems to be plenty of hot sun in summer thoroughly to mature the young wood.

ZENOBIA SPECIOSA.—Figured in one of the earlier numbers of the Botanical Magazine (tab. 970) as *Andromeda cassinefolia*, this very pretty shrub is a native of the Eastern United States. The average height is usually 2ft. to 3ft., but when

growing under very favourable conditions plants exceed this height by 1ft. or more. It is deciduous or semi-evergreen in mild localities. The leaves are shining green on somewhat arching stems. The waxy-white flowers, suggesting those of the Lily of the Valley, but larger, are borne in axillary clusters along the terminal portion of the growths. The variety *pulverulenta* is even more attractive

NODDING WHITE BLOSSOMS OF ENKIANTHUS JAPONICUS.

than the type having glaucous foliage, blue-white beneath. In raising seedlings, which is an easy method of increase, both types and many intermediate forms, usually occur. The flowering season is June and July. *Zenobia speciosa* spreads by means of underground stems, thus providing opportunity for increase by division.

LEUCOTHOE.—This North American genus is included among the *Andromedas* in some gardens and nurseries. It comprises both evergreen and deciduous shrubs. The best known is *L. catesbaei*, an evergreen shrub with slender arching growths, 2ft. to 3ft. or 4ft. high. The small white flowers are freely produced on axillary racemes on the upper half of the stems during May. The variety *Rollisoni* is not so tall in growth and is more compact in habit, with smaller leaves. The young shoots are red in winter and even brighter than those of the species. *L. Davisii* is a most attractive evergreen shrub when in flower. The upright racemes of blossoms are borne in the leaf-axils at the ends of the shoots. The pitcher-shaped flowers are white and freely borne in June on sturdy plants up to 30ins. or 3ft. high. *L. Davisii* is a native of California. *L. racemosa* is the best known deciduous *Leucothoe*. It is a bushy shrub 4ft. or 5ft. high, giving us quantities of white blossoms

during June and is very useful for the shrubbery border.

LYONIA LIGUSTRINA.—This is a free-growing deciduous shrub up to about 6ft. high, more in favourable, moist situations. The white flowers are borne in panicles at the ends of the previous season's growths, and are surrounded by the young shoots of the current year. It is a useful and interesting shrub to naturalise in damp woodland. This *Lyonia*, which is also cultivated under the name of *Andromeda ligustrina* is a native of eastern North America. A. G.

SOME HORTICULTURAL INDISCRETIONS

By MISS GERTRUDE JENKILL, V.M.H.

WHEN one sees some native plant shewing conspicuous beauty or some kind of charm, it is natural that one should wish to bring it into the garden. It may be either of unusual size or colouring, or something that, though quite well known, is not common in one's district, or a plant that has not been seen for a long time and that brings back happy memories of early days. It may be any one of these influences that creates the temptation. But if one who has suffered by giving way, may save others from regretting rash action, these notes may not be without use.

The common Wood Sorrel (*Oxalis Acetosella*) is certainly one of the loveliest of lowly plants and is all the more attractive because it grows in delightful wild places, and especially in sylvan mysteries of natural woodland. But I have never ceased regretting its introduction to the garden, for not only does it increase too rapidly, but it has a way of worming itself into the crowns of plants and Ferns so that it is impossible to dislodge it without breaking up the plant and washing it out. Precious, narrow horizontal ledges, sacred to small alpine Campanulas, attract it irresistibly and there is no way of saving the lawful occupant except by moving the stones and washing it free from the intruder and providing new soil for fear of seeds being left.

Another pretty thing that has become a persistent weed is the Field Scabious (*Knautia arvensis*). During a summer ramble in some pleasant wild ground some plants were found that for colour and size of bloom stood out distinctly from their hundreds of fellows. They were marked and dug up later and put in a garden border, where they thrived amazingly. After the first season, as they had been placed too near the front, they were dug up and put further back. But it became evident that every bit of root tip that had been left in the original place had formed a fresh crown, for the next summer the patch was stronger than before, and all further attempts to clear it out completely failed. Moreover it has strayed into other parts of the garden, where the same trouble goes on. Enchanter's Nightshade (*Circea luteoliana*), though by no means a conspicuous plant, has a certain modest charm that is enhanced by the places where it grows—cool, shady spots near water—dimly lighted—mysterious. But when brought into the garden it positively ramps, with white roots running into other plants and greedily taking up much more space than it was offered. Tansy, which is so handsome in dense masses by the waterside is much too "rooty" to be safely admitted to the garden, but is admirable for wild, watery places.

By far the worst offender, however, is the great yellow Loosestrife (*Lythymachia vulgaris*), a pest that, once established in light soil, has proved impossible to be rid of. It is not common in my

There is a very fine specimen of the plant which has been growing in the garden since it was first brought to the garden. For, besides the place where it was originally planted, it has spread, by what means I cannot guess, as it is never allowed to seed, to a number of different positions. We try to yank it up in small, visible pieces of root must remain, for it appears again and again when one

thinks it has been got rid of. It seems so hopeless that now we merely tug it up whenever it has grown high enough to present a good hold. Many people are baffled by Goutweed, but Goutweed has, at least, visible white roots, and I can undertake to clear it in any open ground, though not when it has got into the roots of shrubs that are not to be disturbed.

thought it had been got rid of. It seems so hopeless that now we merely tug it up whenever it has grown high enough to present a good hold. Many people are baffled by Goutweed, but Goutweed has, at least, visible white roots, and I can undertake to clear it in any open ground, though not when it has got into the roots of shrubs that are not to be disturbed.

GOLD MEDAL GRAPES AND LATE AUTUMN FLOWERS AT VINCENT SQUARE

It has been one of the most unfavourable years on record for the grape grower, so the exhibit at the Royal Horticultural Society's Fortnightly Meeting on November 13 last was all the more meritorious. In the opinion of the fruit experts there assembled it was decidedly the finest collection of Muscat of Alexandria Grapes that has been seen this year of any of the shows. Not only were the bunches large and shapely, some were said to weigh over 4lb., but the berries bore that rich amber colour that eloquently tells of high-class cultivation and rich flavour. The Hon. Vicary Gibbs sent eighteen bunches of these excellent Muscat of Alexandria Grapes and half a dozen of Cooper's Black equally shapely and of shoe-black colour. This variety is much like Gros Maroc in general characteristics. The exhibit, which was placed in the centre of the hall, was, in view of the season, well worthy of the gold medal which was awarded

A highly coloured collection of Apples was staged by Messrs. J. Cheal and Sons, and many valuable varieties were exhibited. The chief sorts were Court Pendu Plat, Gasconne's Scarlet, Cox's Orange, Blenheim Orange, Paroquet, Buxted Favourite and Incomparable.

The Fruit Committee did not make any award for a novelty, though they considered a few. An Apple named C. B. Stuby was sent by Mr. Thomas McPhail from the County Education Department, Dorchester, with the claim that it keeps in good condition till June, so the Committee expressed the desire to see this variety during that month. It is a medium-sized culinary Apple, pale skinned, but flushed on the sunny side.

In competition for the Bunyard medal, which was offered for the best flavoured new Apple, Messrs. Laxton Brothers shewed Lord Lambourne, and the Committee asked that it should be sent to Wisley for trial in the commercial fruit garden there.

A new red seedling Potato was sent by Mr. I. Buchanan, who said it was earlier than Puritan. This new variety is to go to Ormskirk for trial.

Chrysanthemums again took first place among the floral exhibits. Messrs. W. Wells and Co. had a very imposing group of such exhibition Japanese varieties as William Rigby, Mrs. R. C. Pulling, Mrs. Harold Wells and Majestic in tall stands against the wall. On a lower level there were many good singles and baskets of White Cheer, Primrose and Golden Butterfly, three valuable small-flowered sorts. Sulphur Queen, Roma Baylis and Dr. J. M. Inglis were the principal exhibition varieties staged by Messrs. Keith Luxford and Co., and three attractive Singles included the white Nona, Caledonia (mauve), Florisel (dull cardinal) and Sussex (yellow).

Carnations were particularly bright and beautiful. Messrs. Allwood Brothers had a glowing stand of their vivid Edward Allwood, and also staged

SINGLE CHRYSANTHEMUM PINK BEAUTY (MAUVE PINK).

THE BRIGHT CRIMSON CHRYSANTHEMUM MISS JOYCE MOORE

Maine Sunshine, George Allwood, Mrs. Walter Hemus and the delightful crimson-splashed Chintz. Their little bowls filled to overflowing with *Dianthus Allwoodii* were particularly charming.

Crimson Carnations were prominent in Mr. C. Engelmann's collection: Tarzan, Donal and Topsy being especially vivid. Messrs. Stuart Low and Co. specialised in those of pink shades.

AN ATTRACTIVE DWARF WILLOW, *SALIX BOCKII*.

and in the centre had several vases of the Hon. Nita Weir. Eileen Low of similar colouring was also very fascinating.

Messrs. Barr and Sons had a splendid collection of Nerines, and many of the visitors were entranced by the size and rich pink colouring of Aurora. Of the other sorts, Nancy (deep pink), Mrs. Thursby (deep salmon), Lady Acland (rose), Red Hussar and Mrs. Molesworth (rosy cerise) were of great value. These cool greenhouse bulbous plants are really of very easy culture and should be grown by everyone who has a cool greenhouse, as they produce flowers of uncommon type during the dull season.

A good batch of *Primula obconica* in distinct named varieties was exhibited by Mr. E. H. Causer, who also shewed greenhouse Cyclamens and the fragrant *Bouvardia Humboldtii* with greenhouse Ferns in great variety.

Violets of especially good quality were brought by Miss E. Heathcote. She had many bunches of the single variety Princess of Wales, and we do not remember ever before having seen such long, stout stalks. The flowers were of beautiful colour and most delightful fragrance. Mr. J. J. Kettle had a good variety of Violets, which included some seedlings. There was a single variety of real Cambridge blue colour and a double just a shade darker. He told us that, although unnamed, there was already a great demand for them.

The hardy plant growers are experiencing a very dull season just now, and most contented themselves with the fascinating little conifers used for planting in the rock garden. Mr. G. G. Whitelegg had a very good collection and also shewed a batch of one of the capitata Primulas which gave a note of rich purple, contrasting well with the crimson berries of *Skimmia japonica*. The Orpington Nurseries Company also had

many little conifers, and Mr. J. Klinkert shewed topiary specimens.

In a small general collection of hardy shrubs Messrs. L. R. Russell, Limited, included attractive standards of *Enonymus latifolia alba* and some graceful, freely berried bushes of *Cotoneaster pannosa*. Mr. F. G. Wood and Messrs. Bakers, Limited, both included bunches of hardy

C. Radiant.—A valuable market Japanese variety of almost recurved type. The flowers are of formal type, good substance, and orange buff colouring with rosy purple flushing on the older florets. Award of merit. Shewn by Mr. H. J. Jones.

Salix Bockii.—This, one of the most attractive of dwarf Willows, was represented by a couple of small plants exhibited by Messrs. J. Cheal and Sons, both apparently female. The male form is decidedly the more decorative, but any shrub which habitually flowers at this season must have value.

Odontoglossum Ithone.—A beautiful arching spike evenly furnished with large, rounded flowers regularly marked with bright chocolate on ivory white ground and flushed with rose on the backs of the segments. There is a bright golden crest. First-class certificate. Shewn by Messrs. Charlesworth and Co.

Odontoglossum Purple Emperor.—A fine plant bearing three very large, perfectly formed flowers was shewn. They are of rich purplish crimson colour with a gold crest, and the beautifully waved lip is margined with white. A silver-gilt Lindley medal was recommended. Shewn by Mr. H. T. Pitt.

SINGLE CHRYSANTHEMUMS

THE varieties of so-called Single Chrysanthemums at present in cultivation might be divided broadly into five classes:

Class 1 would include those with recurving florets and might be subdivided again into (a) those with one row of florets (true singles), of which the white variety *Mensa* may be taken as typical, and (b) those with several rows; these latter are mostly new varieties and we may take Mrs. J. Palmer described on this page as typical of this set.

Class 2, with saucer-like blossoms formed of regularly arranged broad-ended florets and typified by the old variety *Edith Pagram*, is sufficiently distinct from the smaller, less formal varieties with incurving petals of which *Mary Richardson* is an example to justify the placing of the latter in a distinct group which we will call Class 3.

In Class 4 we have flowers which are bluntly conical in form, with florets which are practically straight, though they may recurve a little at the tips. The florets in this case are, as a rule, on the narrow side and rather pointed, and the petals are usually somewhat uneven in length, giving the blossoms a shaggy appearance. This class again may be divided into (a) those varieties with one row of petals and (b) those with several rows.

To Class 5 must be relegated the quill petalled *Stella*, which is almost a single counterpart of the spidery *Rayonnante*.

Beyond these, again, we have the Anemone-flowered varieties, which may be said to be single in feeling and which vary a great deal among themselves. They, too, may be broadly divided into two classes, the exhibition sorts (a), typified by *Aphrodite*, being very readily distinguished from the graceful spray-flowered varieties (b), of which *Mabel Weston* may well stand as the type.

It is well that we should sometimes take stock and decide where we stand, so to speak, and whither we are going. The great majority of the new Singles which are coming forward belong to Classes 1b and 4 and it may be well to consider whether these represent in fact the most beautiful types possible with this flower. *Mensa*, when it first appeared, attracted admiration by the unusual smoothness and seemingly machine-made regularity

Chrysanthemums in their exhibits of such as *Helenium cupreum* *Crimson Beauty*, shrubby *Veronicas*, *Erigerons*. Mr. Wood also shewed his miniature rock gardens.

We were reminded that the month was November by a number of exhibits of garden pictures of varying merit and a considerable length of tabling devoted to garden design. Miss G. Dorrien Smith received a silver Grenfell medal for water-colour drawings shewing the subtropical character of the gardens at Tresco, Scilly Isles, and Miss D. H. Monray Reid a bronze Grenfell medal for a few very admirable pen and ink drawings of flower sprays and berries. Mr. Percy S. Cane, the well known garden architect, also received a silver Grenfell medal for a collection of photographs shewing charming gardens of many types completed to his designs.

NEW AND RARE PLANTS.

Chrysanthemum Mrs. J. Palmer.—This is a large Single made up of several rows of substantial white florets which gracefully recurve at the tips. Award of merit. Shewn by Mr. G. Carpenter.

C. Miss Joyce Moore.—A very handsome large Single variety. The broad florets are slightly rolled at the tips, giving them a pointed appearance. The general surface colour is a bright crimson lightly flushed with maroon and relieved by a small golden zone. Award of merit. Shewn by Mr. G. Carpenter.

C. Norman.—Another large Single. The broad florets are of good yellow colour lightly margined with rose, and they recurve at the tips. Award of merit. Shewn by Mr. G. Carpenter.

C. Pink Beauty.—This is a large Single with a big solid centre and stippled with washy lilac. The form is more attractive than the colouring. Award of merit. Shewn by Mr. G. Carpenter.

of the arrangement of the florets round the disk; it certainly did not represent an advance in its recurring form—quite the reverse. It is, no doubt, unsafe to argue about questions of taste, but to the writer, at any rate, a composite flower with the florets for the most part level with disk, and actually falling behind it at the tips, has lost all the life and much of the grace which might dwell in it. Then, to add to it several rows of petals, making it practically a decorative type with the central florets removed, can only be still further to degrade it.

This much of Class 1; we approach Class 4 with a great deal of respect, and it must be admitted that the better varieties in it are very charming indeed, yet raisers would surely do well to bear in mind Class 2 and let us have more stout-petalled varieties of the Pagan type, with almost rudbeckia-like flowers. These are distinct and handsome, long lasting and, owing to their substance, excellent market flowers. We still, from time to time, get varieties belonging to Class 3, and really await an improvement in class in this type; substance of blossom and strength of foot-stalk are not, so far, quite what one could wish.

Class 5, though fragile, has many admirers and my new varieties will, no doubt, meet with a favourable reception. It is almost unnecessary to add that any additions to the ranks of the Anemone-flowered varieties will be welcomed by that great mass of Chrysanthemum lovers which has no

interest in exhibition varieties but loves the Queen of Autumn for her decorative value in the conservatory and on the exhibition table.

Nothing has been said about early-flowering Singles for flowering in the open border. The omission was intentional. The writer's advice to those who may contemplate growing them is that of "Mr. Punch" to those about to marry! There seems no reason why a satisfactory strain of early-flowering Singles should not be evolved. A hundred and one forms of Chrysanthemum roseum, which we call Pyrethrums, stand up valiantly to the elements and the same may truly be said of the very numerous forms of CC. maximum and leucanthemum, and there can be little doubt that a really

early-flowering Edith Paganum would weather an autumn blast and a heavy sprinkle of rain. The early-flowering singles that we know, however, are frail things with petals of a similar texture to those of the "Japanese Mountain" varieties, which are now on their trial and which, no doubt, should have been included in our classification. They would have to be graded as Class 4c. Possibly, readers who grow these single varieties for purely decorative purposes might be willing to assist other readers by submitting lists of what they consider the best varieties, giving at the same time the classes in the foregoing notes into which they fall. R. V. G. W.

PLANTS THAT ARE WORTH A PLACE

MOST of us have our idle, or, shall we say, leisure, hours, during which we love to wander in our dream garden. Free from the trammels of actuality and such mere details as soil and sticks and stems, we picture the things we should like to do and the things we should like to have. A special joy comes to the hardy plant lover in reviewing the many "new" or—to coin a word—"unpossessed" plants that he has seen, either at a show or in another garden. And from this review or from reading up one's notes (oh! those fatal notes!), there emerges an array of desirables that one "simply must" have. I always sort and re-sort, by mental criticism of this and that, until this "simply must" stage is reached. Imagining this, that and the other—here, there and everywhere, until quite sure that just that! . . . just there . . . is what is really required.

Having gone through a course of these revisions and excisions lately, here are some notes on a wide variety of hardy plants that are certainly worth a place in any garden, and, whether this is small or great, the floral year will be richer by their addition. First of all, come three of Mr. Herbert's Pinks: May Queen, a bright pink that is excellent as a cut flower, and leaves nothing to be desired either in size or freedom. Lyric as a colour is simply superb, that strong rich purple which really does satisfy the colour craving. Imperial is a delight, either at the extreme front of the mixed border or in the rock garden, where its dwarf habit, intense crimson scarlet colouring and delightful fragrance endear it to all.

Swinging right away from border plants to the climbing Clematis, let us be extravagant and procure a plant of The Bride. This, among all the other whites, stands forward prominently as a good thing, with very fine white blooms and yellow stamens, while the point that especially appeals is its remarkable freedom in flowering. It is an early bloomer and one must not cut away any of the old wood, for it is this that bears the buds and flowers. Let us to the rock garden again, for it is here that we shall see that glorious little Campanula Bellardii Miranda in perfection. Happily it is an easy doer and not troublesome to grow, while it is covered with a profusion of bloom from June to September, quite a point in making the rock garden attractive after the early summer glory has dimmed. Its habit is a good one. From close tufts of foliage dozens of thin wire-like stems push out, bearing large bell-formed flowers of an exquisite shade of silvery blue. When one has finished satisfying the eyes, one has only to bend down to discover a still further attraction, the scent, for one is immediately conscious of a breath just like honey. For a limitless supply of splendid cut flowers, there is a useful plant in Perry's variety of Coreopsis grandiflora. This retains all the good qualities of the type plant, but has, added to these, semi-double blooms that open widely, are on long

stems and last well. As to the freedom with which these appear, one need say but little, for its parentage is a sufficient guarantee in this direction.

Flaming June has been made even more brilliant than of yore, since we have had that wonderful Oriental Poppy, Lord Lambourne, and one cannot wonder that it is making its way into more and more gardens. It is not the colour, though that is vivid enough for anything—so far as orange scarlet is concerned, but the wonderfully deeply fringed and lacinated edge of each petal that at once draws attention to it. Just a few flowers, set up by themselves in the right surroundings and the right kind of vase, form a picture indeed.

When one begins to wander in the autumn garden among the fine Michaelmas Daisies, then indeed confusion does become more confounded; for there is a host of inerituous forms. Among our own "musts," however, is Aster Amellus King George, with its large trusses of bluish-violet flowers of truly remarkable size, and Perry's White. The latter is fine, where a medium variety is wanted, and in the forefront of the white varieties. The flowers are often 2½ inches across, with snowy white petals and a golden-yellow central disk. It is interesting to watch this disk as it ages and gradually becomes a deep maroon crimson. Grand as are the magnificent Kniphofias, with their wondrous blaze of glowing "pokers" when summer is passing to autumn, do not let us overlook the dainty charms (that are especially revealed in small beds or borders) of the gracilis hybrids. The "pokers" of these are remarkably dainty and shew a wonderful variation in colouring from citron yellow to brick red and orange scarlet.

Those who favour "double" flowers should make a note of that splendid Ox-eye Daisy, Chrysanthemum leucanthemum plenum. This is very hardy, free to flower and fully double, while it has the further claim upon us that it blooms twice during the season. May and June see it covered with a grand display of flowers that are greedily cut by the home decorator; then comes a period of rest followed in autumn by a further period of flowering. The Erigerons are so generally useful that a variety with the merits of Merstham Glory cannot be passed by. This is not only a good blue that flowers continuously, but its habit is not too tall, while the flowers are often quite double, thus lasting well when cut.

Viola gracilis in Huntercombe Purple has provided us with a really splendid little edging or bedding plant, the rich clear purple of which is not a colour to use sparingly or in little dabs, but which should be used in broad sweeps, so that the small flowers may have their chance to shew us what they can do when massed in their thousands. With all their "faces" fronting one way, they form a picture indeed, and it is astonishing, if one picks a single flower and looks from that to the massed plants, how clear a demonstration we have of the power of numbers. H. W. CANNING-WRIGHT.

SECTIONS OF TYPICAL SINGLE
CHRYSANTHEMUMS.

CORRESPONDENCE

THE IMPORTATION OF PLANTS INTO CANADA.

AS information to the public of Great Britain in general I might inform you that the Canadian Government, by an Order in Council, has passed a law whereby we in the Dominion are prohibited from importing plants, bulbs, etc., from the Mother Country, unless—after supplying our Department of Agriculture at Ottawa with the information as to consignor, value of plants, etc., and a description of same—we are able to procure a permit to import. We can only ship here by express, as importing through the mail is prohibited. This means that the amateur specialist will for the most part cease to import, and our gardens will suffer, as we shall be compelled to depend on "stuff" we can procure from the big nurserymen in this country. We gardeners and garden-lovers on Vancouver Island and in Vancouver City are taking this matter up with our M.P. for the Dominion Legislature, and have a petition in circulation to try to have the iniquitous Order in Council wiped out at the next meeting of the Dominion Legislature. Is there anything that can be done from your end to help us? I might add that this seems to be the work of some few nurserymen in Eastern Canada, as I am sure it did not originate from the West.—NORMAN W. F. RANT.

[It is very difficult to see what can be done "at this end"—to use our correspondent's phrase. Any representations made by our own Government would need to be of the most tactful character, as the Canadian Government would, naturally, resent anything which could possibly be construed as interference in their domestic concerns.

At the same time we are bound to say that such Orders are very unfortunate. Very many people will question the *bonafides* of the promoters, just as they did, and do, in the case of the similar law which exists in the United States of America.—ED.]

RHODODENDRONS AND STABLE MANURE.

I APOLOGISE for having inadvertently used the words "stable manure," which, I quite agree with my critics (THE GARDEN, November 3, page 569), would not likely prove a suitable dressing. I have never tried it, however. Of course, what I had in mind and what I have been using was cow manure. No doubt "R. J. F." is correct in saying that moisture at the roots is a most important factor to all Rhododendrons, and this is gained by the use of manure as I suggest, but whether by its

moisture-retaining qualities or the suitable ingredients, certain it is I find that they prosper with it.

I cannot say I think, provided the roots are kept moist, that sunshine or shade makes much material difference, always on the understanding, of course, that the plants have not been caught by frost, in which case sunshine in many instances is fatal. As a general rule, my experience is that it may be taken that those with large leaves prefer more shade than those with small leaves. Of course sunshine in Scotland is a somewhat scarce commodity, and it may surprise some of your southern readers when I say that during the last three months I have registered here, in Renfrew-

A CLEMATIS FROM SEED.

shire, within a fraction of 2 ins. of rainfall, so that it can readily be understood that the sun has got but little chance to shine; this year, of course, has been quite phenomenal.

I noticed at Leonardslee, the late Sir Edmund Loder had quite a number of his Rhododendrons packed with bracken, the object of this being, I presume, that in the event of a severe winter the plants might only be killed down to the protecting line, and would sprout again. The idea seems sound. The same idea is practised at Formakin, but in this instance it is in order to prevent rabbits barking the stems. I am sorry indeed that that monarch of the race, *R. Aucklandii*, is absolutely impossible with me here. *R. Falconeri* struggles for existence, but after all what is there but interesting leaves and that only in its youthful years, for in old age its small foliage is but ill compensated by the very third rate blooms? I think, possibly, *R. Loder's*

White, taken all round, is one of the most satisfactory to grow in our northern clime.

I do not know that Sir Herbert's insinuation that Rhododendrons growing in their natural state, get no manure means that they would not be the better with it. Many a small boy would be the better for a good spanking who never gets it. Eh?—FORMAKIN.

WIND-SWEPT SEASIDE GARDENS.

IN case anyone should be misled by the small misprint, may I point out that, in an article on page 575 in which I recommended certain species of *Metrosideros*, I meant that they are suitable for a "really mild" not a "really wild" seaside climate. They will stand a lot of wind, but little frost.—Z.

CLEMATISES FROM SEED.

IT is, I think, unusual to see a well grown plant of Clematis, such as that in the accompanying photograph, and to learn that it has been raised from seed. This method of propagation has much to recommend it; it is simple, and full of interest, for new and often very beautiful varieties are produced and the young plants have all the vigour that seedlings generally show. In the case of the plant photographed, seed was saved from a specimen grown in a cool greenhouse, as in the North it is unusual for the Clematis to ripen its seeds in the open. When seed is obtained (many nurserymen now offer it for sale) it should be sown in early spring, or better still, as soon as gathered, in pans of light, rich soil, and be placed in gentle heat. If a greenhouse is not available, it will succeed in a cold frame, but this delays germination, which is at best slow and irregular.

When the seedlings are of a size fit to handle, they should be pricked off into small pots of good light soil, and kept in them until the pots are full of roots, when the young plants may be shifted into pots a size larger, and grown on in them till they are strong enough to put out into their permanent quarters. The seedlings flower in from one to three years time; all of them are charming and, in many cases, equal in beauty to the finest of the named varieties.

Plants raised from seed seem to be free from the disease which so often attacks young grafted plants. All the seedlings from the batch of which the plant in the photograph forms one, have grown well and vigorously and proved useful and decorative when they came to maturity. The photograph was taken on November 1 and the flowers remained beautiful until November 8, when they were destroyed by too frost.—L. S. T.

WHAT ARE ALPINE PLANTS?

IT would seem desirable once more to call attention to the loose way in which the term "Alpine" is very frequently given to rock and other plants which are in no sense alpine, however suitable they may be for planting with alpine and sub-alpine species on a rockery or in a moraine. The question is admittedly unimportant, but in many cases the use of the term in catalogues and in the horticultural press is misleading.

Mr. Hadden, consciously or otherwise, was so frank as to preface his excellent list by saying "no true lovers of alpine will ever quite agree as to the fifty 'best' plants for the rock garden"; and he supposed criticism was invited on a correspondent's "selection of the fifty plants best suited to the average type of rock garden (including a small moraine)." And "Purley" gave a "list of fifty best alpine . . . though one or two are not perhaps best described as alpine." It would be nearer the mark to say that a quarter of his should not strictly be so described. The same proportion, or a larger one, in the other lists recently

hold of these plants are not alpine in any sense. Quite a number of plants of the foot in southern countries. I doubt if such genera as *Convolvulus*, *Erodium* and *Helichrysum*, to mention a few, comprise any alpine species (they certainly do not in Europe); and by what stretch of the imagination can forms of *Erica*, *Campanula* and *E. vagans* be considered alpine? Certainly Boraginaceae again has remarkably few alpine plants in any Continent.

Of course hardy-plant nurserymen were the first sinners in listing as "Alpines" useful little plants from the Mediterranean, from Italy, Greece and the hills of Asia Minor, etc. But is it too late to ask that the term "rock plants" should be used more frequently?—H. STUART THOMPSON.

NERINE BOWDENI OUTDOORS.

WE all know by repute that *Nerine Bowdeni* will grow and flower outdoors at the foot of a south wall and in favoured localities, but not all of us have seen it so growing. Even after this year's disappointing summer, however, it has

NERINE BOWDENI, AS FLOWERING RECENTLY OUTDOORS AT KEW

flowered quite well against a warm greenhouse at Kew. Is it too much to hope that we may ultimately get a strain of many-coloured *Nerines* which will prove as hardy as, if not harder than, the species in question, and which will flower outdoors in a favourable aspect in the Midlands and Eastern Counties of England? An immense amount of work has been done with the *Nerine* but there is an immense amount still left to do.—N.

FIFTY BEST ALPINES.

IN response to your invitation to criticise "Parley's" list of the fifty best alpine, before giving my list I should like first to ask him if he really flowers the following plants well, which he includes in his list. If so, I should very much like to correspond with him and learn how he succeeds with plants which are so notoriously difficult. The plants in question are *Aquilegia alpina*, *Cyananthus lobatus*, *Daphne rupestris*, *Ranunculus glacialis* and *Viola Bertolonii*. Also, is he able to call them permanent? The list I

would suggest for those who wish for plants of a fairly permanent character is as follows: *Acemum macrophylla*, *Acantholimon venustum*, *Ethionema Warley Rose*, *Alsine verna* fl. pl., *Androsace lanuginosa*, *A. primuloides*, *Anemone Pulsatilla*, *Artemisia pedemontana*, *Asperula suberosa*, *Campanula Bellardii* Miranda, *C. excisa*, *C. muralis*, *C. Stansfieldii*, *C. turbinata*, *Convolvulus mauritanicus*, *Cytisus Ardoini*, *Dianthus gallicus*, *D. subacaulis*, *Dryas octopetala*, *Erodium corsicum*, *Erythraea diffusa*, *Gentiana Lagodechiana*, *Geranium sanguineum lancastricense*, *G. Traversii*, *Gypsophila repens rosea*, *Helichrysum bellidioides*, *Hypericum Coris*, *H. empetrifolium*, *Iberis saxatilis*, *Iris cristata*, *I. gracillipes*, *Lithospermum prostratum*, *Ourisia coccinea*, *Oxalis enneaphylla*, *Phlox amena*, *P. reptans*, *P. subulata* (varieties), *Polemonium carneum*, *Potentilla Tonguei*, *Primula frondosa*, *P. Auricula alpina* (true), *P. Julia*, *P. marginata*, *P. minima*, *Raoulia australis*, *Saxifraga Aizoon baldensis*, *S. oppositifolia*, *Veronica repens rosea*, *Wahlenbergia serpyllifolia* major, and *W. vincaeflora* or *Viola calcarata*.

In making this list I have adhered strictly to plants which are comparatively easy doors, and which for the most part present a compact and interesting form of growth when not in flower. In concluding I should like to add that I have a plant of *Androsace pyrenaica* growing out of doors which has flowered well these last two springs, and that around it have sprung up eight self-sown seedlings which are all growing well. I thought this might be of interest to your readers, as I believe this is rather a rare occurrence.—H. STEWART WACHER.

THE BREAKING OF TULIPS.

IN the last issue of THE GARDEN I received (October 6) I see that Mr. Dykes is storing his Tulip bulbs in paper bags to see if that will prevent them "breaking" by keeping aphids off them. I have kept mine in paper bags for the last three or four years, but I am sorry to say it has not prevented some breaking. Also, I have never observed aphids in the bulbs when drying off; owing to our dry summers the bulbs are generally

quite dry when lifted and require very little drying off, so they are only exposed for a short time. If "breaking" is a disease, how is it that the bulbs do not die out? I believe Zomerschoon has been known for 250 years, and is probably the result of breaking, but is still growing, though I understand still scarce. If breaking were a disease, it must be either a bacterial or fungoid one. Have microscopic sections of broken bulbs been made to see if they are different from unbroken ones. I think from my own experience that broken bulbs do not increase so well as the breeders from which they came, which looks as if they were weaker, but the flowers and foliage when growing look strong and healthy and as big as those of others. It would be interesting if someone would plant the breeders and their "broken" progeny side by side and see which produced the bigger crop of bulbs, note if breeders planted near broken ones broke more than similar breeders planted some distance away, and also if spraying the foliage to destroy aphids, etc., would help in preventing breaking, and if dusting the bulbs with some powder to prevent insects attacking them when drying, would help. I, like Mr. Dykes, have no time for the work, but it should not be a very onerous one, and there ought to be some tulip-lover who had the time or the necessary assistance to do it, and if once settled it would be a great help.—C. T. HILTON, Port Alberni, B.C.

APPLE DELICIOUS.

SOME years ago there was a vote in THE GARDEN on which were the best Apples. Since then I have been growing in my garden here an American Apple called Delicious, and I enclose you one for your comment as to its quality. I think that it is quite up to its name.—W. F. M. COPELAND, Southampton.

[The Apple sent was of excellent quality, yellow fleshed and juicy, with a very pleasing spicy flavour. It would be interesting to know as to its growth and freedom of fruiting. If satisfactory on these points, this must be one of the very few Transatlantic varieties which are useful on this side.—ED.]

CLIMBING MME. ABEL CHATENAY.

MANY of the old Tea Roses may be seen under glass attaining a height of 15ft. to 20ft. and even more. I remember seeing at Hatfield an old plant of *Souvenir d'un Ami* reaching to the roof of a lofty conservatory. The conditions under glass favour this extended growth. I have seen a plant of *Alman Cochet* on a wall outdoors covering a space of fully 12ft. high, and once in Guernsey I saw a plant of *Marie Van Houtte* on a wall outside fully 20ft. high. Only a few weeks ago I saw at Rayleigh in a private garden a huge shrub of *Anna Olivier* fully 7ft. high and as much through.

As to *Mme. Abel Chatenay* making the growth mentioned, it is not at all uncommon. Had Mr. Dean planted the true climbing form, which my firm introduced, it would have made a far more vigorous growth. Our *Climbing Chatenay* will make the first year (as maiden plants) growths 7ft. or 8ft. long. If we bud, say, a thousand of this variety we obtain fully 60 per cent. of this length, but there are also some reversions which, although not "running," as we term it, yet are stronger than the ordinary dwarf form. This happens, as every grower knows, with most of the climbing Hybrid Teas.

The "rose specialist" referred to evidently was not a commercial grower or he would not have made the statement attributed to him. Until we introduced the *Climbing Chatenay* there was nothing to compare with the growths it will

make, so we truthfully claim that we were the first to introduce a true climbing form of this grand old Rose. I frequently advocated in the columns of THE GARDEN some years ago the growing under glass of the so-called dwarf Tea and Hybrid Tea Roses. They are far more useful than the extra vigorous climbers. It treated on the sparse pruning system one may soon cover with them a wall of a greenhouse, or if they be planted in tubs they can be trained on to the roof and one obtains a more continuous blossoming than from the climbing kinds. For outdoor walls and even for the up-rights of pergolas, Climbing Mine, Abel Chatenay stands unrivalled, as can be proved by the great demand for it.—WALTER EASLEA (of W. Easlea and Sons).

[The rose specialist referred to is a commercial grower, if one who grows rose trees for sale as a sole means of livelihood comes within the definition!—Ed.]

THE EARWIG

WHETHER the subject of the sketches is entirely injurious to the interests of the gardener it is very difficult to say. There is no doubt that it is mainly a vegetarian and that the expanding and expanded blossoms of the Dahlia and Chrysanthemum are frequently mutilated by it. On the other hand, it is stated

AN ADULT INSECT ON THE LEFT AND A YOUNG ONE ON THE RIGHT.

that it has been known to attack small caterpillars. It is, at any rate, uncertain if this occurs often enough to be of any practical use.

In any case, it is a great annoyance to all growers of those blossoms which are perfected towards the end of summer and early autumn and, owing to the presence of its very unobtrusive wings, it is difficult to stop its depredations.

Spraying with insecticide may be a certain discouragement to their efforts, but needs to be supplemented in other directions. Pieces of bamboo, with openings into the hollow parts between the joints may be suspended among the plants it is desired to protect and will probably be thought less conspicuous than the usual reversed flower pots, containing moss, upon stakes. Either trap should be immersed each morning in foiling water.

In spring the female lays some oval yellow eggs in quiet corners, under stones, etc., and if a plentiful batch of future earwigs is not desired it will be well to turn over stone heaps and loose bricks, boards, etc., and scatter insecticide freely among them at frequent intervals from that season until the frosts arrive.

There is much to admire about the earwig: the manner in which the wings are folded and packed away under two small scales behind the

THE WHITE-FRUITED SPINDLE TREE.
A FEW years ago I heard of the existence of a variety of our native Spindle Tree, *Euonymus europæus*, which had its fruit capsules white and the seeds scarlet. The description given was most alluring but the plant was evidently very rare, as enquiries in the most likely sources proved vain and its whereabouts remained a mystery to the writer. More recently further enquiries led to its discovery, and it is pleasant to know that it is now being offered for sale, though not at either an exorbitant or a low price. It is not difficult to picture a good plant of the Spindle Tree bearing numerous fruits shewing the striking contrast between the snowy waxy capsules and the bright scarlet seeds or to picture what its effect would be if judiciously planted against a dark background. Many will welcome this Spindle Tree, which boasts of the name of *Euonymus europæus fructu albo*.—S. A.

thorax is very wonderful and the wings themselves, which may be easily expanded on a freshly killed earwig with a pin or two, are marvellously beautiful. Then also the mother shews a great devotion to her young, brooding, feeding and caring for them for a considerable period. The young ones are active from the first and have a general, though not exact resemblance to their parents. In common with other creatures of the same class, young earwigs increase in size until they become literally too large for their skin. This then ruptures and all limbs and appendages are withdrawn from it so that when the process is complete the old skin appears like the phantom of its late inhabitant. On hatching the larvæ are white, but gradually get darker until they first moult, when they again become almost colourless. This alternation of colouring continues with each change of skin. The larva develops into the pupa, becoming more and more like the adult—wing cases and even rudimentary wings being present in the later stages—until the perfect form is assumed with the last moult.

Although apt to hide in dark corners, the earwig has no special desire to enter the human ear. Such an occurrence would be as unfortunate an accident for the earwig as the person, and for the latter might be quickly remedied by filling the

MALE EARWIG IN FLIGHT.

ear with salad oil until the intruder was floated out, which is the safest method of treating any insect intrusion into that organ.

The presence of so many earwigs in autumn is probably due to the fact that no trouble is usually taken to hunt either the adults or young during spring and summer.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Broccoli.—Early Broccoli should be examined twice each week, and those plants approaching maturity may have the curds covered to protect them from frosts. As a rule a few of the outer leaves placed over them will suffice, but if we experience much frost more protective measures should be taken. A good plan is to heel the plants over with the heads pointing to the north, at the same time covering the leafless part of the stem with soil. If necessary, mats or fern bracken may be used, but should be removed when the weather is favourable.

Mustard and Cress.—Make occasional sowings in boxes or pans, and arrange them in a warm greenhouse. This salad is very useful during the winter months.

Celery.—The latest batch of plants has been growing freely during the autumn months and, if not already done, the final earthing up should be taken in hand. Choose dry weather, make the soil fairly fine, and press it firmly between the plants.

Lime.—We are often told to place manure on the garden, but seldom is lime mentioned, yet its value is beyond doubt. It will benefit all soils, and especially those of a heavy retentive nature. The lime should be placed in an open shed and remain there until it is slaked by the action of the air, when it may be run through a sieve. A heavy application is not advocated, and a safe dressing would be from 40z. to 80z. to the square yard. It is best applied in winter when the plot is free, and in the form of a fine powder rather than in coarse lumps. The lime should remain on the surface, there is no necessity to cover it with soil.

Cauliflowers.—Where these are pricked out in frames it will be advisable to admit plenty of air when the weather is fine and mild; in fact, the lights should be removed whenever possible, and the plants kept hard and short jointed. Remove any decaying leaves and weeds, and lightly stir the soil at intervals.

The Flower Garden.

Violets.—If Violets in frames are to go safely through the winter, they will need attention in regard to ventilation. This is very important, because, if a close, moist atmosphere is maintained the foliage is sure to become weak and damp off. Remove dead leaves and lightly stir the soil with a small hand-fork. Traps should be laid for slugs, and the lights may be covered with mats when the nights are frosty. During mild weather air may be admitted both day and night.

Gladioli.—The early-flowering Gladioli are excellent plants for furnishing a supply of cut flower from May till July, and they include Colvillei, The Bride, Ackermanni, Peach Blossom and Crimson Queen. Select a spot sheltered from cold winds and where the soil is not too heavy. Plant the bulbs 4ins. or 5ins. deep, and if we experience much frost, the bulbs should be protected with a layer of leaves or any light material.

Ranunculi.—The double turban Ranunculi may be planted from now till March, but where the soil is of the ordinary garden type the earlier the planting is done the better. The Giant French are planted in February or March. They will make showy clumps in the borders, while on the rock garden they are very effective. They may also be placed in lines 6ins. to 9ins. apart and about 2ins. deep. The tubers should be arranged claws downwards and 4ins. apart.

Fruits Under Glass.

Strawberries.—The bulk of the plants in pots ought now to occupy a cold frame, plunging the receptacles in ashes to the rims. The pots should be set on a hard bottom or a good layer of ashes to prevent worms penetrating the soil. Admit plenty of air; in fact, the lights may be removed except during heavy rains and when the weather is frosty.

Forcing Strawberries.—If ripe fruit is required early and the necessary facilities are at hand, a start may be made during the next few weeks. A low pit, where it is possible to make up a mild hot-bed reasonably near to the roof glass, is the best place. When the temperature of the bed is 50° or slightly below that figure, the pots

may be plunged in the material, for it should be remembered that mild bottom-heat is essential for early forcing. Where fruit houses are started early the plants will succeed tolerably well on shelves if these are not too far from the glass. For the first batch, the plants with the best crowns ought to be selected. Pick off all dead leaves and see that the drainage is in good condition; while, if red spider is present, it will be necessary to cut the foliage in XL. All insecticide. Careful watering is necessary, both extremes being avoided. Gentle forcing is advisable: a high temperature at the beginning is fatal, and 50° would be ample to start with, the temperature being raised a few degrees two or three weeks hence.

The Hardy Fruit Garden.

Apricots do not receive the attention in this country that their merits deserve, although in many gardens will be found a wall with a warm aspect where Apricots could be grown successfully. The variety *Breda* is a very hardy kind and may be grown as a standard. The soil should be well drained and not too heavy, but retentive soils can be made suitable by the addition of sand, old mortar rubble and leaf-mould. Unfortunately, the Apricot loses some of its main branches occasionally, and, so far as I am aware, the cause and remedy have yet to be found. Fan-shaped trees are best for a wall, and for a few years they should be carefully trained until they have filled their allotted space. Established trees should have their growths cut back to three buds to produce fruit-bearing spurs. These will form on all the main branches, and should be about 6 ins. apart. Trees that have become unduly overcrowded with fruit-spurs will need to be thinned but only a few spurs ought to be removed in one season. Vacant spaces on the wall can be filled with some of the young growths, no pruning being needed.

T. W. BRISCOE

(Gardener to W. K. Fyssaght, Esq.),
Castleford, Chapstow, Gloucestershire.

NORTHERN GARDENS.

Vegetables Under Glass.

Rhubarb.—If Rhubarb is required about Christmas-time, a few of the roots which were lifted and exposed should be placed in an intermediate temperature. Some soil should be worked in among the roots under a staging, or other means be taken to obscure the light. The soil should be maintained in a moderately moist condition. Lift and expose more roots.

Seakale.—Keep an eye on the early batch and begin to use as soon as it is fit, as the quality quickly deteriorates. Introduce a fresh batch about every three weeks. Any plants still in the open and intended for forcing should be lifted now, prepared as previously advised, and stored in sand or light soil in a cool frost-proof structure.

Mushrooms.—Keep a sharp look-out on the beds and use the produce as it becomes fit. Prepare materials for future work. See that the stable manure is in a moderately moist condition. Shake it loosely into a conical heap, wait until it begins to ferment and then repeat the operation. It is not fit for forming the beds until it has fermented the second time. When turning the beds—which should be 2 ft. deep—shake the fermenting material into position with the garden fork and beat it firm with the back of the fork as the work proceeds. Finish by placing a 2 in. layer of yellow loam on top of the fermenting material. Thrust a stout pointed stick into the side of the heap, and by pulling it out and feeling it one can judge when the bed is in condition for introducing the spawn. It is safer to have the material on the cool rather than on the hot side.

The Flower Garden.

Seed. Seeds that have been suspended in bunches in some suitable structure should now be separated from the seed-pod, made up in packets, correctly named, with any other necessary details attached, and stored away in the seed cupboard ready for sowing in due course.

Pyrethrums, especially the singles, are among the most useful of our June flowers for filling vases. They should be divided and replanted every three years, otherwise they begin to deteriorate. Although somewhat late in the season, this work may still be proceeded with where necessary, as the plants will do better treated now than they would if the operation were delayed until spring.

Hydrangea hortensis. This showy plant proves all but hardy in the milder districts. When once established it will stand a good few degrees of

frost with impunity, but, if severe frost threatens, the plants should have a mat wrapped round them, and this will generally be found to be sufficient protection.

Sweet Violets will now demand close attention should the weather prove changeable. The frames should be freely ventilated on all favourable occasions, but, on the other hand, protection should be given whenever severe weather sets in.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Salvia rubescens is now in flower, and is deserving of more general cultivation for the cool greenhouse or conservatory. Well grown plants attain a height of 5 ft. or 6 ft., and produce their long, graceful sprays of bright red flowers in great profusion. Even when the flowers have fallen, the dark red calyx lobes are very attractive. A large group in flower at the beginning of the month has been in flower for some weeks, and was raised from seed sown during September of last year. They were sown at this time with the idea of getting the plants in flower before the winter fogs came on. In the ordinary way seed may be sown early in the New Year, or this plant may be propagated by means of cuttings. As it is a strong-growing plant generous treatment is necessary, and 10 in. pots should be employed for good large specimens. During the summer months the plants should be grown in a cool house, or they may be stood outdoors. If placed outdoors they should be kept well staked and tied to prevent damage from high winds.

Salvia leucantha is also now flowering. It is very distinct, and should be more generally grown for winter flowering. This species is easily propagated by means of cuttings during the spring.

Ardisia crenata.—This neat evergreen plant with its wealth of scarlet fruit is very useful for conservatory decoration. The fruit lasts in good condition for well over six months. A batch of plants should be raised from seed each year, as this plant takes three years before it first flowers and produces fruit. It grows quite well in any good potting compost, and is best grown in a temperature of about 55°, although, when in fruit, the plants stand quite well in an ordinary cool greenhouse.

Succulent Plants. This term in a broad sense embraces a wide range of plants, such as *Mesembryanthemums*, *Agaves*, *Aloes*, *Cotyledons*, etc. Many of the smaller plants are very useful for the small greenhouse, as, on the whole, they are not exacting in their requirements. During the dull days of winter most of them require very little water, although that section of *Mesembryanthemums* which includes *MM. Bolusii* and *Lesliei* require more water during autumn and winter, as that is their growing season. During the winter months dry atmospheric conditions should be maintained.

Viburnum Tinus.—Although hardy in the South, this plant is very useful for furnishing the cool conservatory during the winter months. Small plants placed in pots are best for this purpose. During the summer they should be grown in the reserve garden, from which they may be lifted at this time and placed in suitable-sized pots.

Viburnum Carlesii, with its deliciously scented *bonvardia*-like flowers, is very useful for conservatory decoration during the spring months. This plant will stand gentle forcing, but this should not be overdone or it may cause the flower-buds to drop. This fine *Viburnum* is usually grafted on stocks of *V. Lantana*, and a sharp look-out should be kept for shoots springing from the stock. This plant may be grown from cuttings, young half-ripened shoots rooting readily in a cool case during the spring months. Although they root readily, they require rather careful handling to get them established when they are first potted off. *V. Carlesii*, of course, is hardy, but as it flowers early the flowers too often get damaged by late spring frosts.

Manettia inflata (syn. *M. bicolor*). This slender climbing plant is very useful for the cool greenhouse, as it flowers more or less all the year round. Small plants are very useful for the stages, while quite large specimens can be grown if the plants are potted on into 10 in. pots. The shoots should be kept neatly tied to suitable supports, or they may be trained up wires under the roof glass. This plant is easily propagated by means of cuttings at any time, the cuttings rooting quite

readily in a case with slight bottom-heat at command.

Passifloras are very useful for draping rafters in the conservatory. They are somewhat rampant growers and require frequent thinning out. As most of them will now have finished flowering, the growth may now be partially shortened back to allow plenty of light to reach the plants standing underneath. *Eynford Gem* is one of the best tree-flowering varieties. It has been in flower all summer and is still producing quantities of its reddish wine-coloured blooms. Many of the greenhouse *Passifloras* are either varieties or hybrids of *P. corulea*, which is sweetly scented. The fine white-flowered seedling variety *Constance Elliott* is a general favourite, and in the South and West is quite hardy outdoors on warm walls. *P. racemosa* with its beautiful scarlet flowers is generally regarded as requiring stove treatment, but really succeeds quite well when planted out in an ordinary heated greenhouse. *P. Hahnii*, although its flowers are by no means showy, is worth growing for its attractive foliage. *P. Imperatrice Eugenie*, a hybrid between *P. corulea* and *P. quadrangularis* or *P. alata*, is a strong-growing variety which has long been grown in gardens, but it requires a rather large house to see it at its best.

Royal Botanic Gardens, Kew.

J. COUTTS.

BOOKS

The French Iris Conference.—There has just been published the Transactions* of the Commission delegated last year by the Société Nationale d'Horticulture de France to hold an International Conference on the genus *Iris*. The Conference was, it is pointed out, originally intended for 1915, the idea having first been brought forward by the late M. Philippe L. de Vilmorin. The postponement was, it is scarcely necessary to point out, brought about by the war. The year 1922 was, however, in some ways an appropriate one, inasmuch as it represented the centenary of the raising of the first varieties of garden Irises by M. de Bure.

This book, of upwards of 200 pages, divides itself naturally into two parts—the Transactions proper, including plants exhibited, excursions to nurseries, a selection of the twenty-five best varieties and similar selections of fifty and 100 sorts, a list of new and little known varieties and another of those most appreciated in the United States of America, and a calendar showing the season of flowering of the various classes in the neighbourhood of Paris. A large and valuable collection of water-colour drawings of Irises was submitted to the Conference by Mme. Philippe de Vilmorin.

Papers read at the Conference and here reproduced include "Some Results in Hybridisation of Bearded Iris," by Mr. A. J. Bliss; "Hybridisation among Irises," by Mr. W. R. Dykes; "The Range and Distribution of Colour in *Pogoniris*," by Mr. R. S. Sturtevant; "How I Obtained Vigour and Branching Habit in Iris Raising," by Mr. George Yeld; "Species, Varieties and Hybrids of Irises of the Groups *Oncocyclus*, *Regelia* and *Regehocyclis*, *Niphium* and *Juno*," by Mjnhr. C. G. van Tubergen; "Garden Strains of the Bulbous Irises: Sections *Niphium* and *Juno*," by Mjnhr. Ernst Krelage; and "The Use of Iris in Medicine and Perfumery," by Miss Helen E. Ricketts. All these, except the contributions by Mjnhr. van Tubergen and Krelage and Mr. Dykes are in English. There are a great number of equally valuable papers included in the book by such French authorities as MM. Mottet, Laplace, Guillaumin and Gerôme. Soresly as one is tempted, it is not feasible to make quotations in the course of a brief review. Suffice it then to say that no one really interested in the genus *Iris* should fail to procure a copy of this Report.

* "Société Nationale d'Horticulture de France—Commission des Irises: Les Irises Cultivées (Actes et Comptes Rendus de la Première Conférence Internationale des Irises tenue à Paris en 1922)." Published by the Society at 84, Rue de Grenelle, Paris. Price 12frs.

MORE ABOUT FERTILISERS

Guanos, Bone Meals, Dried Blood, Fish Manures, etc.

MANY gardeners, who dislike "chemicals," feel themselves more at home with so-called artificials of an organic nature, and for various purposes these are certainly as serviceable and are perhaps sater than chemicals of uncertain strength. Guano is a term that every youngster who takes up gardening learns, and loves to use as a sign of acquired knowledge, and it is amusing to hear the enthusiastic youthful horticulturist advising his friends who are not of the profession to give their plants a dose of guano, or perhaps relating the remarkable results that have followed the "Head's" dressing of guano on the Chrysanthemums or the Onions. It is about eighty years ago since guano was first brought to Britain and for a good many years its name took such a hold on the fancy of gardeners that any sort of concentrated manure in meal or powder form was called guano, and very hazy notions prevailed as to what the nature of guano really was.

The original guano was simply the accumulated filth of the haunts of countless sea birds that congregated among the rocks of the coast of Peru and other distant shores, and consisted of a conglomeration of the bird's excrement, moulted feathers, dead birds (old and young) egg shells and broken eggs, and grit from the feet of a myriad birds. Hardened by time and the constant patter of webbed feet the manure was found in layers of apparently inexhaustible extent, and being rich in all the principal elements of plant food it rapidly became tremendously popular, and it is on record that in one year almost a quarter of a million tons were imported. Partly through the rapid consumption of the apparently inexhaustible supplies, and partly, it is to be feared, through the avarice of unscrupulous merchants, a good deal of faked and adulterated guano was distributed; to such an extent, in fact, that guano lost much of its prestige and gardeners sought something new.

This gave our chemical manufacturers their chance and brought about the introduction of various excellent compound manures in concentrated form. Many of these have long maintained well deserved popularity under such names as Native Guano, Isthemic Guano, etc. We have also, for some years past, received from reputable importers the real Peruvian guano and other natural guanos in an unadulterated form, their variation in analysis being due to age and situation of the deposits rather than to treatment.

It may unhesitatingly be stated that a good sample of guano is about as good as any fertiliser, the range as well as the quality of the plant food contained being such as to make it suitable for most crops and plants. There are two classes of guano, one of which contains a comparatively large percentage of phosphates and a low percentage of nitrogen, and the other a high percentage of nitrogen and less of phosphates. Phosphatic guano is particularly serviceable for such crops as Tomatoes, Potatoes, Onions, also for Strawberries and bush fruits and for Dahlias, Chrysanthemums and other plants that produce numerous and substantial blooms. Nitrogenous guano is more suitable for Ferns, Palms, green vegetable crops, Celery, and anything that is required to support an ample display of foliage.

BONE MANURES.

The term "bone meal" is another that is commonly used, but is sometimes a misnomer, for there is a wide distinction between the various forms of bone manure. Bone meal proper is made by grinding

bones to a particular state of fineness, which may vary from coarse $\frac{1}{2}$ in. cubes, $\frac{1}{4}$ in. or fine meal, and so to the so-called bone flour, which is bone reduced to a fine powder, free from any sizeable pieces. Raw bones thus ground are most suitable for light soils, but not such as are heavily impregnated with chalk or lime, for the lime will hamper the decomposition of the bone and therefore will delay the solution of plant food.

For limestone or chalk soils it is, consequently, preferable to use dissolved bones. These are obtained by spraying a heap of bones with sulphuric acid. The acid attacks the gelatinous matter in the bones, causing them to crumble into small particles, at the same time it brings the phosphates into a readily soluble form, and thus forestalls the adverse effect of contact with lime.

Bone manure forms an admirable dressing for young fruit trees just attaining bearing size, and is equally valuable for older trees that require nourishment on account of the soil under them being cropped. November and December are excellent for dressing fruit plantations because the bone meal or dissolved bones will have time to liberate their nourishing elements by the re-awakening of the trees. The value of bones to Grape Vines is, perhaps, too well known to require emphasis, but for vine borders it is well to use not smaller than $\frac{1}{2}$ in. bones. Five or even six pounds of $\frac{1}{2}$ in. bones may be used per cubic yard. This quantity will release about as much plant food the first year as three pounds of fine meal, but the residue of nourishment will be slowly liberated during the second and third years—a decided advantage in the case of so permanent a feature as a vine border. Roses derive much benefit from bone manure, as also do herbaceous plants, vegetables and Grass. It is always worth while when laying a lawn on rather poor soil to rake in four to six pounds of bone meal per square rod when finally levelling for turf laying.

FISH MANURES.

There is a great deal of nourishment for plants in decayed fish or fish offal, but, unfortunately, it is so malodorous that it cannot be recommended for use in gardens near habitations. On isolated kitchen gardens or allotments fish offal will give a wonderful return for outlay, but it should be dug in now where the ground will be fallow through winter and be planted with Potatoes or green crops in spring.

There are manufactured fish meals on the market that are both more agreeable to use and quicker in action than crude fish offal, and these also constitute excellent fertilisers for vine borders, fruit plantations and the general vegetable quarters.

DRIED BLOOD MANURE.

It must be admitted that dried blood is rather unpleasant to use, but apart from that one blemish on its character it is a most economical and thrifty fertiliser, gentle but lasting in its effects and suitable for practically any class of plants. One has the satisfaction of knowing that practically the whole bulk of a dressing of dried blood will eventually become soluble, and available to the plants. Some considerable time elapses before results are noticeable, and on that account late autumn and winter are good times to apply it where plants will be making early spring growth. Four pounds per square rod makes a good dressing and where only surface feeding is possible 2oz. per square yard evenly distributed and hoed in will shew good results. Dried blood has a marked effect upon bright, rich colours and may be used to good

purpose on red or crimson Roses, Dahlias, Antirrhinums and many other flowers.

HOOF AND HORN SHAVINGS.

Whoever owns a garden near the village blacksmith should make an effort to obtain a supply of the parings of horses' hoofs and dig them in as soon as convenient. The parings are serviceable on any soil and continue their benefits for three years or more. They are particularly valuable on hungry sandy soil and encourage stiff sturdy growth in all classes of plants. The sawdust from factories where horn and bone buttons, knife handles, etc., are made is also a useful fertiliser; especially for mixing with the potting soil for Chrysanthemums, Hydrangeas, Fuchsias and Pelargoniums.

ONE OR TWO OTHER FERTILISERS.

There are still other fertilisers of distinctive character which have claims to attention. Wellson's Plant Food is a manure that we have used for many years with abundant satisfaction. It is giving no secret away to state that its basis is sheep dung combined with the combings of fleeces. It is carefully treated to evaporate all useless moisture and then pulverised so that the excrement and the wool are reduced to a powder and thoroughly intermingled. The wool is still there, however, and in addition to its own rich elements it possesses, as is well known, great absorptive capacity. Therefore, when the beneficent salts in the excrement are dissolved, the particles of wool become saturated and serve as a sponge to hold them available for the roots of the plants.

Wakeley's Hop Manure has advantages to owners of gardens where the soil is of a stiff, stubborn clay, such as that which extends over a large portion of the London area, or again where loose sand or stony gravel has to be dealt with. In either case the absence of humus is even more serious than the paucity of chemical salts, and the hop manure is ideal for adding humus to the soil, while useful chemicals are added to enhance its nutrient value. It is quite unnecessary to deal at length with the various standard fertilisers which have for years been tested and tried and trusted friends of the gardener. Clay's Fertiliser, Bull's Plant Food With's Manure, Carmona, Abunda and quite a number of other compound fertilisers of well known firms are easy and convenient, quick to shew results, and so long as used according to instructions they are perfectly safe. The greatest benefit of the majority of these, however, is derivable from spring and summer use rather than at the present season.

It is customary to speak and think of chemical and other concentrated manures as substitutes for stable and farmyard manure, and so far as the majority of town and suburban gardens are concerned it is almost obligatory to consider them as entirely such. There can, however, be no question that it is immensely beneficial when possible to supplement the applications of these highly concentrated forms of plant food with just a light dressing of stable manure. We must exempt cases where, owing to soil sickness or acidity, lime is used as a corrective and may also dispense with the stable manure when simply top-dressing cropped ground with such things as guano, dried blood or superphosphates. The benefits of stable manure which cannot be adequately supplied by chemicals are the additional humus provided, the warming of the soil and the assistance in the important function of aeration, without which the benefits of any measures of nourishing the soil are to a great extent nullified. Where stable manuring is impossible the use of Wakeley's Hop Manure is indicated, and an effort should be made to bury leaves, weeds and other wholesome but quickly decomposing vegetable matter, sprinkling any chemicals employed along the trenches as the vegetable matter is being buried. A. J. MACSELF.

National Sweet Pea Society.—The annual general meeting of the National Sweet Pea Society at the Royal Horticultural Hall, Vincent Square, on October 30 was well attended. The Committee's report recorded good work done by the Society during the past year. The statement of accounts shewed a loss on the year's working, but as only nine months' income is included against twelve months' expenditure, this deficit is more apparent than real. All accounts are paid and there are a number of outstanding subscriptions, so that the Committee feel confident that at the end of the year the financial condition will be greatly improved. The Henry Eckford Memorial Medal for the year was awarded to Mr. Charles H. Curtis. The annual show for 1924 is to be held in the Royal Horticultural Hall on July 10 and 11. The trials of novelty Sweet Peas have for the past three years been grown by Mr. A. J. Cobb at the University College Grounds, Reading. Next year's trials are to be grown at Syon House Gardens, Brentford, by Mr. F. England. Mr. J. S. Brunton was elected president for the year, to succeed Mr. Edward Sherwood, who has retired after many years. Mr. J. M. Bridgeford was elected hon. treasurer. The secretary, Mr. A. C. Bartlett, 318, Kew Road, Kew, was re-elected; as also were the hon. auditors, Messrs. George Copley, Kay and Co., chartered accountants, 27, Southampton Street, London. All the eligible members of the General Committee, together with Messrs. R. Ascroft, R. Bolton, Dixon, Coates, Wheler and Charles Unwin were elected. The Floral Committee are Messrs. D. Allan, R. Bolton, C. H. Curtis, A. Ireland, Thomas Stevenson, J. Stevenson, H. D. Tigwell and Charles Unwin.

Dwarf Tropæolums at Wisley.—The following awards have been made by the Council of the

Royal Horticultural Society to dwarf Tropæolums after trial at Wisley: Award of merit.—Fireball, sent by Messrs. Nutting, London. Highly commended.—Empress of India, sent by Messrs. J. Carter, Raynes Park.

Hardy Plant Society's Journal.—The second issue (new series) of the National Hardy Plant Society's Journal* (dated November) concludes the first volume. Henceforward the Journal is to be issued as a quarterly. The articles in this number include a very valuable one on Bearded Irises by that well known raiser, Mr. A. J. Bliss, and the first of a series of papers on "Methods of Propagation," the present one treating of seed-raising and giving a very useful table indicating the best times to sow and suitable composts for numerous kinds of hardy plants; this is by Mr. Giffard Woolley. The President of the Society, Mr. Frank Bouskell, contributes an article on "British Plants in the Rock Garden," and other useful features are notes on the new plants of 1921 and 1922 and a short article on staking hardy perennials, while Book Reviews and Correspondence are also included. In a foreword, the Editor appeals for further support for the National Hardy Plant Society, insisting on the immense amount of work which lies to the Society's hand to do, if and when the necessary funds are available. Membership grows steadily, it is true, and many of the members are enthusiastic, and a very considerable influx of members is confidently expected in the near future, also additions to the list of affiliated societies. As, however, these last represent a certain drain upon the Society's resources, there is the more need for a considerable addition to the roll of members.

*"Journal of the National Hardy Plant Society." Published by the Society at 20, Tavistock Street, Covent Garden, W.C.2. Price to non-members 2s. 6d. net.

Osmanthus fragrans (syn. *Olea fragrans*).—Although hardy in the West, this plant, in the colder parts of the country, should be given the shelter of a cool house. It forms a handsome evergreen shrub either in a large pot or planted out in a bed or border in a cool house. The small white flowers are deliciously fragrant, and for this alone it is worth a place in the cool greenhouse. This plant is propagated by means of cuttings of half-ripened shoots dibbled into pots containing sandy soil and stood under a bell-glass in a cool house.

FORTHCOMING EVENTS.

November 20.—Sevenoaks Gardeners' Chrysanthemum Society's Meeting.

November 22.—Royal Botanic Society's Meeting.
—Wargrave and District Gardeners' Society's Meeting.

Answers to Correspondents

FRUIT GARDEN.

APPLE TREE ATTACKED (C. J. L.).—The caterpillar of the wood leopard moth has bored into the stem of your Apple tree. The best method of dealing with this pest (it is still in the larval stage) is to thrust a sharp-pointed wire into the hole so as to pierce the grub.

NAMES OF PLANTS.—C. R. C. Lancing.—1, Chrysanthemum Crimson Pride; 2, C. Crimson King.

NOW..... is the time to plant

MERRYWEATHER'S FRUIT TREES

BRAMLEY'S SEEDLING.

SPECIAL ATTENTION GIVEN
TO ALL FRUIT GROWERS.

DON'T FAIL TO PLANT

Bramley's Seedling

The Most Satisfactory Apple Grown.

The Merryweather Damson

AN EXCELLENT CROPPER. The fruit is of enormous size, with the true Damson flavour.

Currant Southwell Red

It flowers very late, and so escapes late frosts. Long bunches of bright shining red berries are formed, the individual berries being very large and uniform in size. When gathered it has a very fine appearance and commands the top price in the market.

Price 8d. each; 7/- per doz. Extra strong, 1/- each; 10/- per doz.

LET US HELP YOU.

Advice and quotations free. Send for Catalogue, post free on application.

NEW SPRAYING MACHINES LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete
without a Sprayer, in fact a Sprayer
is absolutely essential to obtain
best results.

During the War we
supplied a considerable
number of our well
known Four Oaks
Knapsack Sprayers—
Rubber Diaphragm
type—to the Govern-
ment, and we have just
re-purchased a small
quantity back again,
which have never
been used. They are

made of copper but painted Service grey colour
They have various special additions to the
ordinary machines, and the price to-day would
be £5 each. We guarantee them to be in
perfect working order as new. We will send
one machine carefully packed, carriage paid,
on receipt of 50/-, but cash must accompany
all orders. We would supply 2 machines
for 90/-, carriage paid.

Please mention this Paper when ordering.

Do YOU know PARSONS'

WORCESTER BERRY ?

If not, you have yet to learn of one of
the most useful berries in cultivation ;

and WHY ?

It has proved its worth as a decided marvel
in berry-bearing fruits, viz. :

As a Cropper.

As a Jam or Jelly Fruit, or for Tarts.

As a resister of Big Bud (or Mite) and Mildew.

Owing to heavy demands I have only a limited quan-
tity, but offer, as far as my stock will permit, as
follows :

Bushes or Single Cordons ..	2/6 to 3/- each
Extra Strong Fruiting Bushes ..	3/6 to 5/- each
Double and Treble Cordons or	
Fan Trained, for Walls,	
Trellis, etc., Extra Strong	
Fruiting	3/6 to 5/- each

Packing and Postage extra, viz. :

1 plant, 9d.; 2 do., 1/-; 3 do., 1/3; 4 do., 1/6; 6 or more,
carriage paid.

It has attracted enormous attention when exhibited at Shrews-
bury, Harrogate, Glasgow and Edinburgh Shows, and the opinion
of some hundreds who tasted it was "a delicious fruit."

If you have not seen above, ask for a copy of my New Fruit
List FREE, with Coloured Plate of my Berry, Press Extracts,
and Testimonials.

My List includes ALL THE BEST in APPLES, PEARS, PLUMS,
etc., and my Worcester Crown FIBROUS-ROOTED Trees may
be relied upon for BEST RESULTS and QUICK RETURNS.

sent on receipt of postcard.

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

Cash Prices (including bags): Small (about 1 bushel), 3/-; Large (about 4 bushels), 7/-; 5 Large, 33/9; 10 Large, 65/-; 20 Large, 120/-.

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond.

BATH'S CARNATIONS, ROSES & PÆONIES.

—New Illustrated Catalogue containing full cultural notes of the best new and standard varieties is now ready, and will be sent post free on application.—(Dept. E), R. H. BATH, LIMITED, The Floral Farms, Wisbech.

DOBBIE'S 1924 CATALOGUE AND GUIDE.

Ready December 15th. Applications now being booked. Mention THE GARDEN.—DOBBIE AND CO., LIMITED, Edinburgh.

IRON AND WIRE FENCING for Gardens,

Tree Guards, Gates, Arches, Espaliers, Rose Stakes and Ornamental Garden Iron and Wirework of every description. Send for Illustrated Catalogue. Also Kennel Railing and Poultry Fencing. Ask for separate lists.—BOULTON AND PAUL, LIMITED, Norwich.

LOWE AND GIBSON, Border Carnation

Specialists, Crawley Down, Sussex. Our Border Carnation service is said, by our customers, to be the most efficient in the country. The smallest order will prove to YOU whether this is so. Thirteen selected plants from 10/6 to 21/-. Postage 6d. Special quotations for large quantities. List on application.

BARGAINS IN GARDEN WIRE !!!—

Government Field Telegraph cable, cost £35 per mile; our price less than a twentieth!! Great for training fruit trees, greenhouses, pergolas, arches, tomatoes, hops, beans, peas, logans, chrysanthus, tying, fencing, etc. Brand new, steel stranded, waterproof covered; several thicknesses from 19/6 per mile (full 1,760yds.). Small lots supplied. Secure a supply in readiness. Postcard to-day for free samples, and list of 320 Bargains post free. GREEN'S BARGAIN STORES, 375, Seymour Road, Lytham.

ROCK PLANTS, best varieties, inexpensive.

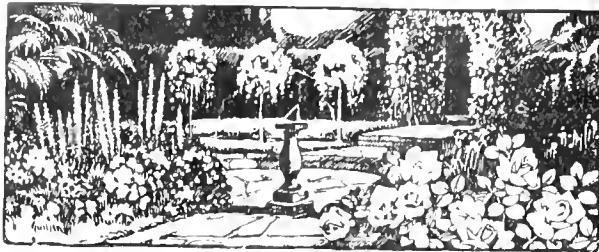

List free.—MARION GLEDSTANES, Fardross, Clogher, Ireland.

ALPINES.—Acantholimon venustum, 2/6;

Astragalus massiliensis, 1/6; Campanula Warley White 2/6; Erodium chamedryoides roseum, 2/-; Hypericum kochyanum, 1/-; Oxalis adenophylla, 1/6; Primula Wictori, 3/-; Sax. Eursiana sulphurea, 2/-; Sax. H. Marshall, 2/6; Soldanella alpina, 1/-; Veronica Bidwillii (true), 1/6; Viola areolaria rosea, 9d. Many others. New Alpine Catalogue post free.—BOWELL & SKERRATT, Nurseries, Cheltenham.

GREENHOUSE PAINTING AND GLAZING.

—"Vitrolite," superior to White Lead Paint, 18 6 per gallon, cans extra. "Plastine," the Imperishable Putty, 32/- per cwt., kegs extra; 7lb. tins, 4/3 post free; 14lb. tins, 5 6 each, carriage extra, tins free.—Full particulars from W. CARSON AND SONS, Grove Works, Battersea.

ALLENS' ROSES

Avoid further failures by replacing with extra Hardy Trees grown on our East Coast Rose Grounds.

Send a card to-day for our Illustrated Catalogue.

ALL LATEST VARIETIES AT REASONABLE PRICES.

DON'T WASTE TIME AND MONEY ON APPARENTLY CHEAP FOREIGN TREES.

All trees **GUARANTEED**:—True to name, Home Grown and delivered in perfect condition.

A. J. & C. ALLEN, Bowthorpe Road, Norwich.

Notes from Maidstone.

GRAPE VINES & FIGS

The best Grapes are described in our list, which is sent free. We will not attempt descriptions in this limited space.

For Heated Houses we have all the best varieties — Muscat of Alexandria, Madresfield Court, Alicante, etc., etc., while for cold houses we recommend Black Hamburg, Buckland Sweetwater, Foster's Seedling, etc. Planting canes 15' - 21' - and 25' - ; Fruiting canes 30' - and 35' - each.

FIGS. — All the best varieties for indoor or outdoor planting. Bush or Fan-trained 10'6" to 21' - each.

Established 1796.

Do YOU know PARSONS'

WORCESTER BERRY?

If not, you have yet to learn of one of the most useful berries in cultivation;

and WHY?

It has **proved its worth** as a decided marvel in berry-bearing fruits, viz.:

As a Cropper.

As a Jam or Jelly Fruit, or for Tarts.

As a resister of Big Bud (or Mite) and Mildew.

Owing to heavy demands I have only a limited quantity, but offer, as far as my stock will permit, as follows:

Bushes or Single Cordons ..	2/6 to 3/- each
Extra Strong Fruiting Bushes..	3/6 to 5/- each
Double and Treble Cordons or Fan Trained, for Walls, Trellis, etc., Extra Strong Fruiting ..	3/6 to 5/- each

Packing and Postage extra, viz.:

1 plant, 9d.; 2 do., 1/-; 3 do., 1/3; 4 do., 1/6; 6 or more, carriage paid

It has attracted enormous attention when exhibited at Shrewsbury, Harrogate, Glasgow and Edinburgh Shows, and the opinion of some hundreds who tasted it was "a delicious fruit."

If you have not seen above, ask for a copy of my New Fruit List FREE, with Coloured Plate of my Berry, Press Extracts, and Testimonials.

My List includes ALL THE BEST in APPLES, PEARS, PLUMS, etc., and my Worcester Grown FIBROUS-ROOTED Trees may be relied upon for BEST RESULTS and QUICK RETURNS.

SOME IDEAS FOR WOODLAND PLANTING

THE possession of a piece of woodland, or of even a small spinney, which can be included in the garden lay-out should be an immense advantage; unfortunately, however, it does not always seem to pan out so. There are numbers of ways in which such woodland can be treated, and perhaps the greatest mistake—and the one most commonly made—is to attempt too much. Well kept woodland has its own natural beauty, but, even here, Nature is not always kind; the tangle of sterile Brambles which one often sees could by no stretch of imagination be called beautiful. Very different is the woodland aisle practically devoid of vegetation in winter but in late spring sheeted with myriads of Bluebells. There is great value in this form of "planting," inasmuch as it detracts in no way from the beauty of the boles of the trees.

„Were we, then, to consider how to get the maximum of quiet beauty from our woodland we should probably leave it very much alone, merely introducing here and there colonies of woodland plants, either native elsewhere in Britain or frankly exotic. Perhaps, however, we have designs upon this stretch of timber to try out some of the many wonderful Asiatic Rhododendrons, in which case judicious thinning may probably be desirable and also the provision of additional shelter from certain points of the compass. The power to visualise a scene when certain particular and bulky features are removed is not given to everyone, and where some trees certainly need removing and there is a doubt as to which should be sacrificed, it is far better to call in expert advice than to run the risk of spoiling the general effect. Many of the Asiatic species of Rhododendrons will ultimately occupy a great deal of space, and they should be planted far enough apart to allow their full development, but there is no possible reason why temporary plantings of other shrubs should not be made to occupy the ground for the lengthy period during which the permanent kinds are growing. Rhododendron ponticum is a beautiful and hardy species for woodland planting,

and forms a splendid screen for more tender sorts, but care should be taken to select a form of pleasing colouring. It is easy (and cheap) to procure plants "for covert planting"—seedlings with no particular colour qualifications—but when they flower a particularly virulent magenta, the purchaser, not the nurseryman, should take the blame. They have now a very pleasing white ponticum at Kew which, so far as the writer knows, represents a new break.

Leaving aside for the moment this question of Rhododendron planting, let us for a while consider

woodland planting in some perhaps more natural aspects. Without in the least destroying the character of our wood or copse we may plant such things as the coloured forms of the Wood Anemone, the hardy Cyclamens, the Dog's Tooth Violets (American and European), Anemone apennina, Scilla campanulata and, in fairly damp spots, the Dodecatheons. The shade-loving Narcissus pallidus præcox should be sure of a place on the woodland fringe where shade is not too dense. Then, while leaving aisles to shew the natural grandeur of the trees, we can introduce

plantings of undergrowth in irregular groupings between them, which, consisting largely of Dogwood, Honey-suckle Azalea, Cornelian and Holly, should add beauty directly by their form and colouring, and at the same time serve to emphasise the height of the trees and, by restricting lateral vision a little, strengthen the cathedral effect we all notice in fine woodland. In addition to all these advantages, and to the plant lover more important, it may be, than all of them, it will form the nucleus of plant groupings which would either be not feasible or else quite ineffective dumped down, as it were, on the open floor of the woodland. Such a grouping, evidently in a rather damp, but by no means boggy, corner is depicted at the foot of page 618. Here Azaleas are used not ineffectively as dot plants.

The Wayfaring Tree, Viburnum Lantana, beautifies many a copse in Southern England, and might usefully be introduced into the margins of woodland elsewhere. Nor is this the only native species which is attractive for the purpose in mind. The Lily of the Valley (*Convallaria majalis*), will have occurred to most people for the purpose, so will the Solomon's Seal (*Polygonatum multiflorum*) and the Foxglove. Other native plants which may not so readily spring to mind are the Martagon Lily (*Lilium Martagon*) the Drooping Star of Bethlehem (*Ornithogalum nutans*), Herb Paris (*Paris quadrifolia*) and the Spring Snowflake (*Leucojum vernum*). The Primrose in its typical form will in some localities be too common to make it worthy of encouragement beautiful though it admittedly is

AZALEA DAVIESII IN WOODLAND.

Many of the hardy terrestrial Orchids are woodlanders, and one of the most beautiful of them all, *Cypripedium calceolus*, was until comparatively recently not too rare in the limestone woodland of the Craven Highlands of Yorkshire. It is almost extinct there now, yet if a healthy plant could be found in the first place, it should not be difficult to cultivate in our cold-wooded woodland where it once grew. In such conditions suit most of the following species, including *C. calceolus*, *areolaris*, *puberulum*, *fasciculatum*, *ovoides*, *virginicum*, *puberulum*, *parviflorum*, *pinnatifidum*, *pubescens*, *puberulum*, but not the North American *C. speciosum*. Such likes were grown at Kew and several other

THOUGHTS ON MICHAELMAS DAISIES

I VISITED a sick man on the eve of St. Martin. The night before, there had been some seven or eight degrees of frost, and what Dahlias there were were a mass of slimy, sad-looking brown, the rows of yellow and other hued Chrysanthemums were lying flat on the ground; their bedraggled blooms had obviously shot their bolt, but a little off on the left of the door there was a bright row of rose looking as unconcerned as you please, as if there had been no soaking week of wind and rain and no nights of trying frost. Of course, I knew at once it was a row of Michaelmas Daisies, and I have since learnt that almost to a certainty the name of the variety was Marne. This, then, is my text—the beauty and utility of the Michaelmas Daisy as an autumn flower. The three “big” children of Flora that come to us modern gardeners in the third season of the year are named Michaelmas Daisy, Chrysanthemum and Dahlia. Each has done his bringing up vast credit. Each has taken kindly to his adopted country and taken out papers of naturalisation. We know them all. We know their good points and their bad points; each of them. Mrs. Malaprop was often muddled and sometimes wise. Never perhaps more so than when she uttered her famous dictum, which, by the way, was not really her own, “Comparisons are odorous.” I leave it at that, lest perchance in the near future issues of THE GARDEN should smell of the sulphur of a wordy war. Michaelmas Daisies have proved their utility this year up to the hilt. It is true that we have had (here at all events) a frostless September and October, but, all the same, the garden has not been an

“island-valley of Avilion,
Where falls not hail or rain or any snow,
Nor ever wind blows loudly.”

—(“The Passing of Arthur.”)

Very, very much the reverse, and yet when I went out this same St. Martin's eve to gather a bunch for a kind lady who had brought us some Flanders Poppies to aid the British Legion I was able to gather quite a nice bunch of Belgian Queen, Brightest and Best, Marne, Ribston, Gladys Donellan, Maidenhood, Blue Star, Bianca, Hilda Mona, even a bit of Edwin Beckett and Climax, to which I might have added others, but the bunch was already large for a lady's hand.

What a season we have had to be sure! What a happy idea it was to fill all the long scar-like beds on the lawn with Michaelmas Daisies! The whole became at a little distance a sea of foam on which Messrs. Sun and Shade continuously played their ever-changing jazz limelight of white and all shades of rose and pink, and all shades of lavender, mauve and heliotrope, now and again almost a blue when it lighted up the Rev. C. Nunn, Blue Gem and Little Boy Blue.

Personally, I do not in the least mind bare beds when I know that it is only a question of time when a transformation will take place and the dingy chrysalis will become a Red Admiral or a Tortoiseshell, or, it might be, a still rarer butterfly of more subdued but just as beautiful colour—a Camberwell Beauty. This is not the way of the world. “Colour all the time; give us colour,” is the cry of the majority. I know how it is, and so, on one scar, I made an experiment. All along the bed in the centre of the double row of Daisies I put rose-coloured Antirrhinums. They looked very well, especially as one stood at one end of the avenue when the Michaelmas Daisies (all *Novi-Belgii*) were starting to flower. I see no reason why the idea should not be extended and enough interplanting done to give three

displays. There might be an early one of something bulbous; then might come the Antirrhinum show, which would last until the Michaelmas Daisies began, and if the seed-pods were cut off from time to time it would not be half bad for a longer period still. I left here yesterday morning. Now, when I resume, I have to chronicle a curious coincidence. My next sentence would have been to suggest Michaelmas Daisies as being one of the flowers that are indispensable if a bright garden is wanted, or if something is wanted to cut for autumn shooting parties. In the afternoon I met a friend. We got on gardening. I said I had had a fine show of Michaelmas Daisies. “I wish,” he said, “you could tell me a few good ones to add to our collection, *we find them so useful for our week-end shooting parties.*” My friend's wife joined in with some such remark as this: “Yes, we find them better than anything for cutting.” They might have been thought-readers. Partridge parties presuppose such varieties as the Rev. C. Nunn (a very blue mauve), Wonder of Colwall (medium mauve), Lavender (large lavender mauve), Lady Lloyd (rosy pink), Jupiter (pale mauve), Pioneer (pink), Feltham Blue (rich blue mauve with an orange centre), Pink Perfection (rosy), King of the Belgians (tall helio), Bees Blush (a fine-petalled deep blush), Perry's White (in my opinion the best white, all things considered, although Maid of Colwall is also good, and Albacross useful because it is so early), Edith Goodwin (a marvel for lasting, blue-mauve), Dainty (a bushy rose), Grey Lady (large, grey coloured, spidery petal) and Ribston No. 10 (small daisy-like pure white, a first cousin to Tennyson's Brook). Good pheasant party varieties are Edwin Beckett (lavender, absolutely “top hole”), Louvain (pink), Climax (pale blue mauve), Sunset (an *A 1* rose), Blue Gem (soft blue-mauve), Connelness and Little Bo Peep (two splendid cordifolius varieties), Bianca (small white, grows like a Cedar of Lebanon with an abundance of horizontal branches), Mons (rose), Maidenhood (a very beautiful pure white *ericoides*), and Esther (dwarf narrow-petalled pink). I might go on and on, but in a more prosaic article I hope, with the Editor's permission, to try to reduce my favourites to reasonable proportions. Few who have never made the attempt know how hard it is to make a selection out of a catalogue. It is not many removes from making a silk purse out of a sow's ear. Hence, when my lists are produced, I hope critics will take this into consideration.

I have another suggestion to pass on to readers. A lady who I know has never been to Japan,

but who evidently has been carried away by the descriptions she has read of the cherry blossom-time there, said, “What a sight it would be to have nothing but masses of pinks and roses! The sight would equal the wonderful Cherry blossom-time in Japan.” I, too, think it would be a fine sight, and if only one could always have the Michaelmas Daisies between the declining sun and ourselves, I doubt if any sight in Japan could surpass it. There are few who would give up the whole of their gardens to carry out the idea, but there may be some part, some isolated bit or odd corner, where the experiment might be made. It will not lack varieties to make the season long, for there is a big space between the flowering of Pioneer and Ribston or Marne. Nor will there be a lack of divers shades from a pale blush like Bees' Blush to the deep rose Brightest and Best. Nor, yet again, will there be any difficulty as to heights. On the low-growing side

THE WELL NAMED ASTER PIONEER.

there are the pink Esther and the pale blush The Pearl—possibly the new Bijou, a pink-mauve, might be judged of sufficient pinkness—while on the tall side we have Louvain. Between these extremes we might make a long list. If neither a garden, nor a part of a garden, nor an enclosure be practical politics, how about a good big bed, something like what we know as a herbaceous border, from 8 ft. to 10 ft. wide and of any length? A round bed of sufficient size would make a fine feature on more or less dressed grass. Naturally, what my friend suggests as a sort of English copy in Michaelmas Daisies of the Cherry blossom in Japan might be changed somewhat, and blue-mauves, mauves, lavenders and heliotropes might take the places of the pinks, roses and blush. They would have a quiet but real beauty.

JOSEPH JACOB.

THE GENISTAS

In garden the popular name of Brooms is used for both Cytisus and Genista. A frequent question asked is, "How can they be distinguished?"

AS a few plants in growth and culture, with their lilac and drab-hues, there is no difference between Cytisus and Genista. The botanists' first point of difference is in the seed. Near the hilum there is a wart-like excrescence in the Cytisus, which is absent in the Genista, or at least not so strongly marked.

The main details in the culture of the Genistas are sunny positions and very well drained soils. It is not advisable to plant Brooms in rich, deeply dug and well manured ground. This produces an abundance of sappy growths, whereas to get well flowered Broom, hard, well ripened branchlets are required. For poor soils and sunny banks the Genistas have few rivals when planted in

large masses. Seeds provide a ready means of rapidly increasing most Genistas. When these are not available, cuttings may be inserted in August. These root under cloches or handlights in very sandy soil. The best wood for cuttings consists of growths 1½ ins. to about 3 ins. long taken off with a thin beel of old wood.

Genistas, because of their long, wiry roots, are not easy to transplant. It is, therefore, desirable to grow the young plants in pots until large enough to place permanently in the flowering positions. There is no need to protect the plants in a frame; in fact, they will do better and are less troubled with the pests plunged in the nursery beds.

The Genistas do not require much, if any, pruning. In the first few years of their growth the tall species—*G. cinerea*, *tinctoria* and *virgata*—benefit by a little shortening of the branches to induce bushy growth.

G. TENENSIS is one of the largest-growing of the genus, varying from 10 ft. to 20 ft. in height. It has very few leaves, and these are quite small, but the bright green branchlets of healthy young bushes are a good substitute for an evergreen shrub. Old specimens become somewhat gaunt, and often they are not upright, but when in flower during July and August some lovers of hardy shrubs would acclaim this characteristic a good feature rather than otherwise. Thinly planted along a wide and open shrubby border, the Mount Etna Broom with its graceful habit is very attractive when laden with its clear yellow blossoms. It is a native of Sardinia and Sicily. A flowering spray is well shown in a coloured plate which appeared in *THE GARDEN*, March 18, 1893.

G. ANGLICA, the Petty Whin or Needle Furze, is a spreading shrub growing up to about 2 ft. high. The yellow flowers are freely produced from May to July. It is a not uncommon plant of our heaths and moors, and is a widely distributed plant over Western Europe. For sunny banks the Petty Whin is valuable and attractive when gay with bright yellow blossoms borne in leafy clusters on the upper branches.

G. CINEREA.—This species is the most attractive of the taller Genistas, flowering freely in June and July, when the majority of flowering shrubs are past. The average height is from 9 ft. to 12 ft. The bright yellow flowers are freely produced in small lateral clusters on the slender branchlets. This Broom is a native of Spain and other parts of the Western Mediterranean region. Though it grows and flowers very freely at Kew in lawn beds, shrubberies and open woodland, I have seen no seeds matured, but cuttings provide a ready means of increase.

G. GERMANICA is a useful June-flowering shrub from 1½ ft. to 2½ ft. high. Widely distributed as a wild plant over Central and Western Europe, this species is distinguished from *G. anglica* by its hairy leaves and branchlets, while isolated plants are more sturdy in habit.

G. HISPANICA. For massing on dry banks and sunny slopes the Spanish Gorse is the most showy and useful plant of the genus to plant in quantity for effect. During the closing days of May and until well beyond the middle of June the rich golden yellow blossoms supply valuable colour. The average height is about 1½ ft. The Spanish Gorse makes an excellent permanent edging for a wide shrubby border in a sunny position, bordering a carriage drive, for instance, and when in flower the plants are frequently covered with blooms. It is a native of South-Western Europe. The variety *pumila* is a valuable dwarf shrub, forming needle-like cushions of greenery for sunny positions in the rock garden.

G. MONOSPERMA being a native of Southern Europe and North Africa, is on the borderline of hardiness, but it is a really elegant shrub for a

GENISTA HORRIDA, ONE OF TWO SPECIES WITH OPPOSITE BRANCHES AND LEAVES.

ONE OF THE MOST USEFUL FOR THE ROCK GARDEN, GENISTA DALMATICA.

GENISTA HISPANICA AT HALLINGBURY PLACE.

low sunny wall or fence. Here, in a warm and sheltered position with light soil, the slender pendent growths are dotted with milky white fragrant blossoms.

G. RADIALA.—Though perhaps not one of the most attractive Genistas in flower, this species is very distinct in habit. It forms a rounded bush of thin, wiry branchlets up to about 2 ft. to 3 ft. high. I always associate this species with *G. horrida* because they are pointed out to the student of botany as the only two hardy Genistas with opposite branches and leaves. The rich yellow flowers attract attention in June. It is a wild plant of Central and Southern Europe.

G. TINCTORIA.—In addition to the dwarf-growing species and the double variety so valuable

in the rock garden, there are several distinct forms of taller habit. The two usually listed in the nursery catalogue are var. *elatio*, a tall, erect growing shrub 4 ft. or 5 ft. high with large panicles of yellow blossoms, and var. *mantica*, earlier in flowering and not so tall in growth, with more or less down on the branchlets and leaves. To keep these true they must be propagated from cuttings. In the garden, seedlings are equally valuable, or more so, because one gets a very variable batch of shrubs flowering most of the summer. As an indication of how this plant varies, the Kew Handlist of Trees and Shrubs gives fourteen synonyms.

G. SAGITTALIS, so named because of its flattened stems, is a very distinct and interesting plant. It is a dwarf species some 6 ins. to 1 ft. high. The

plant is a native of Central and South-East Europe. At Kew it is effectively planted along a gravel walk as an edging to a border, the well drained condition of the position being evidently favourable, judging by its free growth. The yellow flowers commence to open in May and extend through June.

G. VIRGATA is a native of Madeira, and particularly interesting as being one of a very limited number of plants from that island that are hardy near London. It forms a bushy wide-spreading shrub up to 10 ft. or 15 ft. high and as much through. The flowering season is from June to August, with the bushes aglow with yellow blossoms about midsummer. The Madeira Broom was figured in the *Botanical Magazine*, tab. 2265, as *Spartium virgatum*. For light well drained soils it is one of our most valuable tall shrubs for pleasure grounds or open woodland. If the seeds fall in favourable positions there are always plenty of young plants coming up to perpetuate the species.

THE ROCK GARDEN GENISTAS.

G. DALMATICA is a valuable alpine Broom from Dalmatia and near by. It forms low-growing tufts of branchlets 5 ins. to 6 ins. or 8 ins. high with age, covered in June and July with masses of golden yellow blossoms.

G. PILOSA forms a dense-growing prostrate shrub, and is one of the most valuable Brooms for the rock garden, threading its roots between the crevices in the stones with the growths clinging to and hanging over the boulders. The flowering season is May and June—when good clumps form a bright yellow carpet of blossoms—with, often, more flowers in autumn. In addition to being a common wild plant of the southern half of Europe, *G. pilosa* is one of the three British Genistas, the other two being *G. anglica* and Dyer's Greenweed, *G. tinctoria*. The latter is from 1 ft. to 2 ft. high, and flowers in June and July. It is not much grown, however, being quite surpassed as a garden plant by the double-flowered form (*flore pleno*). This is a semi-prostrate plant with rich yellow blossoms lasting in beauty from July to September. In common with many double flowers, the Double Dyer's Greenweed does not produce seeds, but is readily increased by cuttings. A. O.

AUTUMN TINTS IN BERRY AND LEAF

IF it does not always exceed in brilliance of tint some of its rivals, the Maples for example, the old *Azalea pontica* can claim a foremost place among the general run of autumn-colouring shrubs. Individually it may, indeed, sometimes assert itself with a crimson-scarlet so fierce that the most gorgeons of its neighbours must "pale their ineffectual fires." For myself, I always think that the great charm about the autumn tints of this shrub lies not only in the wide variety of rich colouring which the foliage displays, but in the extraordinary length of time for which the display is maintained. This year some groups had surrendered their green for a warm bronzy-purple at the end of August, and from that time onwards to mid-November *A. pontica* will usually provide us with an ever-changing feast of colour. Soil and position, naturally, have considerable influence in deciding the date, as well as the intensity, of the leaf coloration of the plant; those specimens in the hottest, poorest land being the first to yield. For that reason, if for none other, we always grow this old favourite in detached groups in various parts of our woodland garden.

At the moment of writing, the most fiery leaf colour happens to be that of *Berberis Coryii*, a ruby-crimson vivid enough to make *Vitis amurensis* look dull. Near to this comes *B. Prattii*, with its fine fruit clusters, and *B. dictyophylla*, of which the crimsoned leaves are subdued by the glaucous hue that pervades the branches, will not be passed by unnoticed. Among these and others, however, not forgetting *B. vulgaris*, the beautiful little *B. Wilsonae*, which can hardly claim such wonderful leaf colour, can still hold one's admiration and affection. No other species grown here has such charming elegance as this one, in none does the lovely bunches of translucent salmony-red fruits in their setting of fresh green make so strong an appeal.

The birds having suddenly devoured the fruit of most of the more lowly Cotoneasters, which carry their berries so invitingly and conveniently on the upper surfaces of their spreading planes, it is up to the taller and later species to carry on the good name of the race. Among these, *C. Simonsii*, despite the familiarity from which it suffers, can still maintain its ground as a shrub of remarkable beauty at this season. *C. frigida* is carrying clusters of berries like a Mountain Ash,

but they will not remain any longer than those of the latter, and the drooping branches of *C. pannosa* are laden with their ripening crop. If this evergreen species is one of the latest to colour its fruit it is one of the most attractive of the taller members of the genus, a regular and prolific bearer of pendent clusters of blood red berries which hang well into winter, and one that has a singularly graceful habit. The still newer *C. Harroviana* comes close to the foregoing and has a splendid reputation, but it has not yet gone beyond the trial stage in this garden. *C. Franchetii*, greyer in leaf and more angular in growth than *pannosa*, is another good and late-fruited species of the same class as the latter, and the more aspiring, whip-like branches of *C. Dielsiana* can always be depended upon for a good berry crop in the later autumn. The smaller (5 ft.) *C. Zabelii*, a deciduous species with an attractive, arching habit, affords good leaf colour at this season and the comparatively large fruits glow with a bold crimson when, in early November, they have thrown off the downy felt of youth.

Though the rich wine-reds, crimsons and scarlets of autumn foliage may pass in a gradation of

From green to some late shades down to orange, the yellows (which an artist might call greens), are set apart, with a tender loveliness peculiarly their own. The Common Ash, especially in the sapling stage, often affords a good example of this soft, clear yellow, but it has to be seen at the moment of its fullest splendour for the leaves of few trees are so quick to fall. The same primrose-yellow pervades Forsythia suspensa which, grown as a bush against a dark green background, is hardly less bright and attractive than it will be in March when flowers instead of leaves adorn its slender twigs.

The creamy pallor of leaning Bracken and frond of Male Fern gleams with a weird cold light in shadowy places that are dim with the heavy verdure of creeping Ivy, and a somewhat similar tone invests the stately ranks of Solomon's Seal. I think this fine old plant is never quite so handsome as it is at this season and in such a situation as the above. If it can be grown on a level with the eye, the shoe-black fruits which hang below the sheltering leaves will seem to be suspended in a radiance of golden light.

Also very effective in these shady places is the dying foliage of the Funkias Sieboldii and Fortunei, the reds and yellows of Cornus canadensis, the straw-coloured leaves of Anemone trifolia, which have until lately been increasing in size and stature ever since parting with their pretty flowers, and the elegant foliage of the Dicentras formosa and eximia.

A fuller yellow, that of an unripe orange, has taken possession of the Tulip Tree (Liriodendron tulipifera), and the large saddle-shaped leaves of this noble species maintain their colour for several weeks. The Judas Tree (Cercis Siliquastrum) also assumes a good, if more subdued yellow. Cornus florida and Amelanchier canadensis adopt red and gold for their parting flare, and this combination is nowhere more strikingly seen than in some of the Roses, of which the crimson, scarlet and orange fruits enhance the effect of the yellowing foliage. The Ramanas varieties are especially noteworthy in this way just now, but RR. lucida and alpina, which have a finer grace, are not less lovely. Indeed, most wild Roses yield an autumn colour in fruit and foliage, or both, so attractive that a page or two might be written upon this feature in them alone. Yet one cannot pass over the genus without a mention of little R. nitida which, in leaf and stem, becomes fired with a blend of blood-crimson, vermilion and orange more vehement in tone than that of any other member of the race that I have seen.

Although the Azaleas alluded to are second to none in their bronzy and vinous hues, the blue, more plum-coloured shades of purple are claimed by some of the Elders, a few of the Vacciniums and the beautiful lance-shaped leaves which adorn the rigid and upright branches of Forsythia viridissima. Seen in combination with the pale yellow which flecks the drooping, willow-like wands of Exochorda grandiflora, or, as I once saw it in a neighbour's garden, in conjunction with the delicate gold of Ginkgo biloba, this Forsythia was a very beautiful object. Liquidambar styraciflua must also come into the plummed list, and then there is Vitis vinifera var. purpurea, which is a Vine of much more moderate growth than most, and thus suitable for gardens where accommodation for such things is limited. The Claret Vine, as it is called, keeps its foliage in full autumn colour for a month at least in normal weather, and the deep vinous red, just the hue of a ripe Victoria Plum, becomes an intense blood crimson when the leaves are seen against a low sun.

The foliage of most of the ash-leaved Spruces goes off in a subdued orange, and the leaves of

some young specimens of S. arborea are a curious blend of orange and plum-purple, the ribs and veining being of the latter tint. The double-flowered S. prinifolia also has a reputation for colouring well in some gardens, but its efforts in that respect in our own have not been very inspiring. Euonymus europæus, the Spindle Tree, makes a wonderful display when the foliage

has changed to ruddy bronze and the coral-pink fruit capsules gape open to reveal the bright orange-coloured sacs which contain the seed. E. obovatus, the only other deciduous species grown here, is a trailing bush of straggling habit. Its fruits are not as showy as those of our own native, their colour being an unhappy combination of crimson and scarlet. NORTH WALES.

GARDEN DESIGN—IV

Herbaceous Borders.

EVERYONE grows perennials. In extensive grounds there will be long borders filled with great masses of different plants and in the tiny garden they will be grown in proportionally smaller groups or even as separate plants. Herbaceous plants alone might make a garden full of interest and colour for six or eight months of the year, if the selection is carefully made.

Positions for herbaceous borders should be suitable ones. The single border may face south or west, although I have seen some of the most successful under a north wall, especially in a hot, dry summer. Such a position would not be very good for those plants that flower early, but for a summer border, the plants in it would flower for an extended period of time. In borders flanking a turf or other path, and forming a herbaceous walk, there must be a balance of the principal masses, that is to say the eye must feel that the taller groups on one side are properly balanced by the taller groups in the opposite border, and strong colours on side should be balanced by colour of equal strength, although not necessarily the same hue, in the opposite border.

It is well to decide before planting the borders what the colour scheme is to be; for the principal border it will probably be desired to have all the stronger colours—yellows, oranges, blues, reds, etc.—toning to many of their paler shades. Where there are other borders as well as the principal ones, perhaps smaller, there can be other interesting colour schemes, a blue border or garden is always beautiful, especially in the hottest part of the year, or a border of soft pinks, creamy yellows, pale blues and greys might be made very charming.

among or with a background of shrubs, will give effective masses of colour.

Tritomas (Kniphofias) form another particularly handsome genus of plants, their flower spikes in all shades of yellow, orange and red being especially striking at a time of the year when the summer flowering perennials are past their best. There are now such a number of perennial Asters (Michaelmas Daisies) that the difficulty is to know which to exclude, rather than to have the separate borders filled with them. The range of soft colours in Michaelmas Daisies makes them particularly attractive.

There are so many plants with which one can fill the principal borders, all of them almost equally beautiful, that it is difficult to make a selection. Delphiniums may be considered essential, being, indeed, among the aristocracy of the herbaceous world. They should be planted in soil that has been deeply dug and liberally manured with well rotted manure, and then be left undisturbed for several years at least. They are to be obtained from the modest price of 6d. or 1s. each up to, for certain triumphs of the skill of the hybridist, a couple of guineas or even more a plant. It is well when planting these more expensive varieties to guard them against the depredations of slugs or other pests, which seem to have a pronounced liking for their tender young shoots just as they appear above the ground. This can be done by surrounding each plant with a ring of cinder ash, across which the slugs will find it difficult to lay their slimy trail.

For the back of the border, where tall plants are generally necessary, large groups of single and double Hollyhocks may be planted; they are

PLAN FOR A HERBACEOUS WALK.

As well as borders of separate colours or colour schemes, some herbaceous plants are never seen to so much advantage as when planted entirely by themselves, their different varieties being massed in groups proportional in size to the size of the border or ground to be planted. This applies particularly to the taller growing Phloxes, Delphiniums and Michaelmas Daisies. Phloxes grown by themselves in some outlying parts of the grounds,

deep-rooting and appreciate generous treatment, but should be watched for rust, a remedy for which is to spray the foliage with a weak solution of sulphate of copper at half the strength that would be used for potato spraying.

Anelusa italica, with its varieties, such as Dropmore variety and Opal, is another effective plant for the back of the border, where also Verbascums and Tree Lupinus are very valuable.

A HERBACEOUS WALK AT CRANBOURNE COURT, WINDSOR FOREST.

Most of the *Anchusas* and *Verbascums* are but short lived perennials and do best if treated as biennials, young plants being planted every year. After the first season it will probably be found that so many self-sown plants will appear in the borders that a drastic thinning out will be all that is necessary.

Where it is possible, always have dark backgrounds for the borders; an old red brick wall is perhaps the nicest thing possible, but hedges of Yew or Box or even Evergreen Privet can be very good. It is advisable, where there is room, to leave a path of 2ft. or 3ft. between the hedge and the back of the border; the hedge plants will take most of the nourishment from the ground and it will enable the hedge to be clipped and the plants in the back of the border to be staked and tended easily.

Although the lowest-growing plants should be planted in the front and, speaking generally, the tallest in the back rows, yet the groups must be so arranged that there is a pleasing variety of outline, taller plants or groups of plants being brought forward, maybe, into the middle of the border and here and there lower-growing things being carried well back among the medium and taller plants; this will give shadow and that variety of light and shade that is so essential if the borders being made are to be really beautiful. For the same reason, and to give solidity, a few shrubs may be introduced here and there among the herbaceous planting. Green and golden Box and Yews would be suitable with, carefully placed among them, an occasional flowering tree or shrub. Evergreen shrubs, as well as emphasising formal design, will help to furnish borders during the winter, when the majority of herbaceous plants are only in evidence by their short, dark brown stalks, the remains of their summer's growth.

Although principally herbaceous in character the planting for the front of borders in the now so popular paved garden is quite different from that bordering grass walks. In the latter, although the border should be full and plants should grow quite to the edge of the turf, they should not grow actually on to the path. In the

case of the paved garden, plants are intended to grow right on to the paving, and such kinds should be chosen as will do this.

Of these there are a number with a prostrate or semi-prostrate habit of growth that renders them especially suitable for such a purpose. *Nepeta Mussini* is invaluable and the grey leaves and soft pink flower of *Stachys lanata* can be used in tiny gardens. Most of the *Dianthus*es are suitable, and the stronger growing of the dwarf *Campanulas*, the forms of *C. pusilla*, being among the best. *Alyssum saxatile compactum* and the paler variety called *citrinum* may also be planted to grow on to paving, and other equally suitable plants include *Violas* in their different colours. The *Helianthemums* and the dwarf species of *Cistus* give masses of colour and pleasing mounds of foliage for quite a long time. The *Mimulus* (Monkey Flower) has a very pleasing habit of spreading from the border into crevices in the paving; there are several good varieties; *luteus*, a pleasing soft yellow, while *cupreus* and *Wargrave Fire Flame* are respectively coppery crimson and coppery scarlet. These *Mimulus*es are moisture-loving plants and, if given liberal supplies of water, may be relied upon to flower freely for a long time. PERCY S. CANE.

OVERHAULING THE ROCK GARDEN

THIS is the best season to rearrange and, if necessary, partially to rebuild the rock garden, provided the taking up and replanting is executed expeditiously and only during open weather. It is a common failing to the majority of rock gardens to dry out during the hottest months of the year, and in the drought of 1921 many just accepted the inevitable and let things go. Those of us, however, who made notes, mental or otherwise, during that time of anxiety noticed that certain plants pulled through. In every such case the plant was found to have its roots under,

around, between or among stones and rocks. Here, then, was a lesson, the learning of which should benefit us very considerably. Those who failed to learn it have suffered fresh losses in the interim, and should now see that more stone—of a porous nature if possible, but failing such, any kind—is buried throughout the soil in bank, ledge and pocket. This matter of buried rock cannot be too strongly emphasised. The rock which is exposed is very ornamental no doubt, but unless plenty of it, from quite large pieces to fine grit, be buried everywhere in the soil, our rock garden will never be what it should be. Another potent factor in the conservation of moisture is humus. This is best provided by well rotted leaf-mould or old hot-bed material. Half-decayed leaves are quite useless for the purpose; indeed, are likely to accentuate the dryness. Anyone who has tried to moisten partly decayed leaves which have become "bone-dry" will appreciate this point. Do not add the material, whatever it may be, in wads or layers, but fork it evenly throughout the soil. Finally, remember that stone chippings on the surface after planting prevent excessive evaporation. If for any reason these cannot be procured, place some stones immediately round the plant on the advent of hot weather. Where the soil is excessively wet, it will be necessary to put in some kind of drainage, but do not forget to remove all the sour soil and to replace it with fresh.

Another failing many of us probably noticed was the lack of blossom for quite a large part of the year in certain parts of the garden. This is a common fault, and one of the most difficult to overcome. It is due largely to our eagerness to produce certain effects in the way of contrasts and combinations of colour without giving sufficient thought to the duration of flowering, and to our failing to visualise the aftermath.

Again, we may have noticed, and been irritated by, a "spotty" effect, more particularly when the garden was viewed as a whole, and it is in correcting this fault that we inadvertently commit the one mentioned above. In order to remedy this "spotty" effect, it is necessary to plant as far as possible in bold masses and drifts, but in deciding to heighten the effect by a daring contrast of colours we too often commit the error of planting the varieties concerned next to each other, with the result of a large space devoid of colour perhaps for months. There are two ways of avoiding this: (1) By using continuous flowering plants for one of the colours, thus reducing the amount of space left bare of flower. (2) By planting the contrasting colour on a different level but in such a way as to produce the desired effect. "But surely," I hear it said, "it would be a simpler and better way to use two continuously flowering kinds?" This would tend towards monotony, especially so if the effect be one of colour contrast, and monotony is a bad fault in gardening.

Another point which may have struck us as unfortunate was the number of "dot" plants which evidenced themselves in whatever direction we happened to gaze. We frequently see some plant we have not got and instantly covet it, or friends give us from time to time desirable plants. We seldom stop to consider whether we have a suitable spot for them, but just put them in where there is room at the moment, with, naturally, a spotty result. A "dot" plant must possess some striking character before it can justify its rôle of exclusiveness; moreover, it must be in the right place, so let us make a rule—and at least endeavour to keep it!—that we will never acquire a plant we cannot "place."

Possibly we notice, too, an overcrowded appearance due to the planting of too many shrubs and

which probably looked very charming when first planted but have now outgrown the positions they occupy. One should never plant shrubs and trees in a rock garden unless there

is a sound reason for doing so, and then only the most suitable for the purpose and position should be employed. C. S. G.

(To be continued.)

THE VINE WEEVIL

THE vine weevil, *Otiorhynchus sulcatus*, is one of the most voracious and destructive of greenhouse pests, and each year much damage is done by this insect to Vines and Peaches, and also to various pot plants, Cyclamens being particularly liable to attack. During May and June of this year the weevils were very numerous in the West of England and it is probable, therefore, that many gardeners and fruit growers will be troubled with their grubs this winter and on into the spring.

The weevil, which is about half an inch long, is dull black in colour and has a short trunk or snout to which are attached slender, clubbed head feelers or antennae. The legs are stoutish and black and are clothed with dark pubescence. The thorax is coarsely punctured and the wing covers, or elytra, are roughened and granulated. There are no membranaceous wings, consequently the insect cannot fly, and the area over which its depredations occur is somewhat limited. The weevils are to be found in the spring, in April, May and June, their maximum appearance depending on prevailing weather conditions. They feed at night on the green leaves of Vines, Peaches, Nectarines and other indoor fruit, and during the day remain hidden in crevices in the walls, in soil under pots and in other available shelter. The damage done by the weevil is characterised by semi-circular or irregular patches eaten out of the leaves and the tender skin scaled off the young shoots, which may be bitten partly through and remain hanging down from the point of injury. Besides attacking indoor fruits and pot plants the weevil is very injurious to Strawberries and Raspberries out of doors and has been found doing considerable damage to grafts by eating out the buds, usually in association with the clay-coloured weevil, *Otiorhynchus picipes*, which is smaller, but quite as destructive. In a case of a bad attack on Strawberries by these weevils, the writer found that, as well as destroying the young folded leaves in the crowns, the insects gnawed shallow holes in the developing fruit. During the day the weevils hid among the foliage, under the straw or under clouds of soil about the Strawberry beds.

The eggs are white and oval and are laid in clusters in the soil. They vary slightly in shape and size, depending on the position of the eggs in the cluster. Their colour soon changes from white to brownish and they are most difficult to locate in the soil. After some days they hatch and give rise to legless grubs which are whitish, much wrinkled and clothed with hairs or bristles, which facilitate movement. The head is distinct; it is highly polished and brownish in colour and bears strong biting jaws. The young larvæ or grubs are very active and work their way to the roots of plants where they feed and grow, undergoing numerous moults as they increase in size.

The grubs feed on the roots of various fruit trees and bushes and on Strawberries out of doors and indoors at the roots of pot plants. In the case of Cyclamens, they feed at the base of the bulbs and eat out penetrating cavities; decay follows and the bulbs become utterly worthless.

Feeding continues throughout the winter and in the spring the grubs follow out cavities or cells in the soil at a depth of pins, or gins., and after a period of quiescence, change into pupæ or

chrysalids, which are creamy in colour and have transparent outer skins through which the outlines of the developing weevils can be seen. After a fortnight or so the pupa becomes brownish in colour and, finally, the outer skin splits, allowing the weevil to make its way out. After emerging the insect gradually assumes the dark brown or blackish colour of maturity.

CONTROL MEASURES.

When the weevils are found in vineries or peach houses all pot plants, or as many as possible, should be removed; this will prevent eggs being laid in the soil of the pots. Since the weevils have the habit of dropping from the plant on which they are feeding at the slightest touch or jar, it

IMAGO, LARVA AND EGGS OF THE VINE BEETLE (ALL MUCH ENLARGED).

has been found useful to spread sheets of brown paper below the vines or fruit trees during the daytime and at night to enter the house with a brilliant light, whereupon many weevils fall from the plants, disturbed by the light and the rest may be dislodged by sharply tapping the rods or trees. The fallen weevils are easily seen on the paper and should be collected and destroyed. In the spring of 1923 a badly infested vinery in Gloucestershire was cleaned by this method of catching the weevils. Where cracks and crevices occur about the houses they should be carefully searched for weevils: the holes in vineries through which the rods run into the outside border frequently afford shelter and obscurity to numbers of these insects.

Where plants in pots are attacked by weevil grubs, it is advisable to repot them into clean soil, swilling their roots thoroughly to free them from the grubs before doing so.

When young fruit plantations or nurseries are infested with weevils it is advisable to protect the young trees, especially the newly grafted ones, with grease bands; for, since the weevils cannot fly, they are thus effectually prevented from reaching the buds. If, for any reason, this method is not employed, a lead arsenate spray, 1lb. per 25 gallons of water, should be used. Jarring the

trees at night over tarred sheets has been found to yield very good results, especially when adopted on cordon or trained trees.

Where Strawberries and Raspberries are attacked by the grubs, the infestation is difficult to deal with, though spraying as above mentioned is quite satisfactory for checking the adults. The best way of destroying the grubs is by means of a soil dressing made by adding one pint of carbolic acid to one bushel of sifted ashes. This should be scattered over the beds and lightly forked in, one or two applications being made in late August and early September. This treatment will probably destroy a considerable number of young grubs and prevent serious injury. HERBERT W. MILES.

MAKING AN ALPINE MEADOW

WHILE one cannot claim for the "alpine meadow" that it is a novelty, one can at least assert that it is not commonplace nor hackneyed, and also that it does approach as nearly as possible to Nature and Nature's way of growing and displaying many of her most beautiful children. Stated in the briefest manner, what is proposed is to transform a piece of uninteresting short rough turf into a flowerful stretch of meadowland where alpine flowers of suitable growth enrich the spring days with colour and fragrance.

The ideal spot, of course, is a sharply sloping bit of hillside covered with rough turf; but, failing this, a corner in an orchard or any similar spot may be used with good effect. Many of these spots are mown down about midsummer, either with a view to hay or to give an air of neatness, so that suitable plants must be chosen to permit of this. Bulbs readily answer the purpose, which is doubtless the reason why naturalising has made so much greater progress than our alpine meadow; but by a judicious choice of kinds there is no reason why plants should not be used just as freely. A study of our own fields and the plant groupings will do much to enable planting to be done in easy and natural-looking masses, which are far more effective than indiscriminate dottings. Do not forget that in the alpine meadow a far more luxuriant growth is permissible than when dealing with the rock dwellers, so that many "drifts" of taller plants are desirable.

In this connexion do not overlook the capabilities of the old-fashioned short-spurred Columbines. These are among those sturdy plants which are perfectly able to look after themselves and their progeny, and will sow themselves freely all over the place, falling into artistic and delightful groupings without any guidance from us. Anemone alpina sulphurea is a splendid little early Wind-flower that may well be used in company with the better known apennina, which carpets the ground with its sheet of rose, white or blue starry flowers in such amazing multitudes when the April sun is shining. A blaze of starry gold in clear outstanding patches may be secured by the generous use of the *Doronicums*, which serve the double purpose of decorating their own particular bit of the garden and providing a supply of long-stemmed flowers which are ideal for cutting purposes.

The hardy *Geraniums*, sanguineum and pratense, are also both splendid space fillers that never fail to give a good account of themselves. The Martagon Lily, though far from a pleasantly smelling plant, is most striking when seen rising

from among a mass of one or another of these *Geraniums*, and the partnership is in every way a most happy one. If—as was suggested earlier—the ground chosen for such a scheme is a sloping piece, plants of the magnificent *Trollius* or *Globe Flowers* should be used at or towards the bottom, for these are such moisture lovers that it is hopeless to grow them on an elevation. *Viola cornuta* may be planted everywhere, and the sooner it can be encouraged to become a wildling, in fact as well as in name, the better for the charm of one's meadow. This little gem is obtainable in shades of white, pale mauve and deep purple, all equally valuable as a carpeting to the various other plants employed.

For autumn days one may have a rich store of beauty in the various autumn *Crocuses*—which are really *Colchicums*—and the numberless winter-flowering species of the real *Crocuses*, both of

which take no harm at all from the midsummer cutting of the grass. This list of plants might be extended almost indefinitely—are there not the Meadow Saxifrage (*S. granulata*) and a host of other plants that leap to mind?—but sufficient has been said for a start to be made.

As all the plants are absolutely hardy, such work may be taken in hand either in spring or autumn, according to the nature of the soil and the plants, for it will be obvious when dealing with such diverse material that all cannot be put in at one single time or period. The best way of all for carrying out the ideal of the alpine meadow is for this to lead by imperceptible transition from the rock garden, so that as one wanders on and on the discovery is made that the high alpine have been left behind and one is treading the flowery way of an excellent imitation of alpine pasture.

H. W. CANNING-WRIGHT.

FLOWER-POTS AND BULB BOWLS.

HAS the writer of the article on "Flower-Pots and Bulb Bowls" in *THE GARDEN* for November 3 ever seen the Silchester ware bowls and vases? Flower-pots I have never seen. The bowls and vases are made by hand outside Reading. They are of a dark brown colour, slightly glazed and of good shapes, and are supposed to be reproductions of pottery from the Roman villa at Silchester. There is an agency here and I met with them at Cambridge.—(Miss) A. E. ROSS, *Newbury*.

POLYGONUM BALDSCHUANICUM.

I COULD have wished that in his article on the Herbaceous *Polygonums* "W. L." had turned aside a little longer to sing the praises of that splendid and rapid climber *P. baldschuanicum*, as one who has little use even for *P. compactum* or *sachalinense*. An old gardener of mine who grouped them all together as "chock"—he generally eased his feelings in an opprobrious adjective—would, I know, support me in banning them even from woodland, for their advance may not be withstood. *P. baldschuanicum*, however, is a "grey horse of another colour."

CORRESPONDENCE

TULIPS IN GRASS.

I HAVE read with interest in Sir Herbert Maxwell's new book, "Flowers—A Garden Notebook," the interesting information given regarding Tulips flowering in grass at Caerbays Castle in Cornwall. Further, it is most interesting to hear that these bulbs were planted forty years ago. Unfortunately, in most places, it is useless planting Tulips in grass as they cease to flower after a year or two. It would be interesting to know the exact reason why they flower at Caerbays Castle in grass and whether it is due to any special treatment or conditions.—CARDROSS, *Mid-Calder, N.B.*

THE FIFTY BEST "ALPINES."

I HAVE read with pleasure the notes in *THE GARDEN* upon the fifty best alpine, or rock plants, and thought that possibly a list from a Northern garden might be of interest; let me say that it is an exceedingly dry garden, having a deep bed of sandy rubble below. With the exception of the *Helianthemums* I have omitted all shrubs and bulbs, though I should like to include *Daphne Blagayana*. The list is: *Aethionema warleyensis*, *Anemone nemorosa* *Robinsoniana*, *Anthemis Cupiana*, *Arenaria montana*, *Astrantia gracilis*, *Aubrietia* Fire King, *Campanula collina*, *C. pusilla* Miss Willmott and *C. muralis* major, *Cheiranthus mutabilis*, *Cardamine rotundifolia* and *C. pratensis* plena, *Dianthus neglectus*, *D. superbus* and *D. sylvestris*, *Cypripedium Calceolus*, *Erodium chrysanthum* (for foliage), *Gentiana Lagodechiana*, *Geranium Pylzowianum* and *G. Russell* Prichard, *Geum Borisii* and *G. bulgaricum*, *Gypsophila repens* rosea, *Hypericum olympicum*, *Iberis Climax*, *Helianthemum* Mrs. Earle, Jubilee and the single red, *Lychnis alpina*, *Morisia hypogæa*, *Onosma albo-rosea*, *Orobis vernus*, *O. albo-rosea*, *Omphalodes cappadocica* and *O. Lucilia*, *Oxalis enneaphylla*, *O. floribunda* and *O. magellanica*, *Pentstemon Davidsoni*, *Patrinia gibbosa*, *Phlox Sprite* (syn. *Vivid*), *Potentilla nitida*, *Primula Julia*, *P. rosea* and *P. acaulis* alba plena, *Saxifraga Irvingii* and *S. Bursleriana* Gloria, *Sedum stoloniferum*, *Spiræa digitata*, *Veronica saxatilis*, *Viola Alannah*. I recently saw in Mrs. Saunderson's garden at Wenington, a glorious Milkwort called *Polygala calcarea*, a lovely deep blue.—T. O. WALKER, *Annas Bank, Carnforth*.

THE GIANT LILY.

WHEN the beautiful *Lilium giganteum* of the Himalayas was introduced into Great Britain I do not know, certainly it was rather widely

distributed more than fifty years ago, and as it is easy of cultivation and appears to be objectionable to rabbits, it is both a wonder and a pity

THE FREE-GROWING *POLYGONUM BALDSCHUANICUM*.

so few people give themselves the trouble to provide in their pleasure grounds for such an ornament as a group of these stately flowers. An open space about 20 yds. across in a wood or shrubbery, in a cool situation for choice, and if possible in lightish soil, a load or two of farmyard manure, and patience for one year or two, and then a never-ending succession of graceful giants which may well average 1 ft. in height with stems 12 ins. round near the base—some more and some less—clothed with foliage which alone would make them worth growing, all leading up to the fragrant blossoms of which the scent is carried far beyond the sight of this gem of the grove; it is difficult to think of anything better. I have lately seen at Hoveton St. John in East Norfolk, where Mrs. Blofeld lives, an ideal group of nine flowering stems with their candelabra-like clusters of seed-pods and next year's plants among them. The offsets are taken from the old stems and replanted, as otherwise they would not have room to develop well; and by no means may manure be forgotten, and in a season of drought water may be acceptable.—T. REDEN COLWIN, *Ketton Hall, Stamford*.

and quite indispensable where a beautiful screen is wanted quickly, and no one need fear to introduce *PP. vaccinifolium*, affine or *equisetiforme*.—N. H. P.

STILL FROST.

I DARE say there are not many gardeners who welcome the late autumn and the winter months, with their frosts and snows. I don't at least, far from it; but I make a point of snatching from the adversity of winter any "sweet uses" it can serve—the fleeting joy of trees, for instance, under a fresh fall of snow. So also a still frost, such as we have been having for a few nights lately, has its delights—a still frost, be it noted, not a black frost, most hateful of Nature's humours, blown hither by a north-east wind from the Pole. The still frost is that which crusts your window-panes with tropical forests of bewildering perspective, done in ice-crystals. One recent morning when I looked through the ice jungle on my window without being able to see beyond it, I surmised that things in the garden, herbaceous or shrubby, would be finely trimmed with crystal; and so they were. We profess to be fond of grey plants—at

Like *Geraniums*, *Centaureas*, *Stachyses*, *Campanulas* and what not. On a frosty morning the whole garden is grey, each individual species having its leaves and, it may be, even its branches decorated, sometimes with a fringe, sometimes with a hem, and sometimes with a mere gilding or wash of frost. Take, for instance, a flat leaf of some size, a leaf, say, of Foxglove or *Verbascum*. In its ordinary unfrozen state you would never have supposed that the leaf had all those corrugations—so many, relatively speaking, deep valleys and lofty eminences. But the frost gives a Rembrandtesque emphasis to the relief of a rough leaf, leaving the valleys, where, low down, run the veins, in green shadow, and “gilding” the heights with a wash of silver. Very different is the frost effect on the Mossy Saxifrages. We are too apt, some of us, to lump the Mossy Saxifrages as things much of a muchness as regards foliage; but the frost discriminates each pattern sharply—stag’s horn, rosette or mossy spray. No need to leave the matter. Each plant has its own way of getting frozen. *Berberis Darwinii*, for instance, makes a light and graceful spray. But the two most sensationally beautiful effects in my garden that morning were those produced by *Senecio Greyi* and *Cotoneaster horizontalis*. Those who grow the *Senecio* will have perceived how in the small canoe-shaped leaf the silver of the undersurface is brought round to form a narrow hem on the dark upper surface. The effect of a still frost is to make this hem into a fringe of icicles, while the valley of the canoe remains deep green. As for the *Cotoneaster*, with its fan branches, scarlet berries and frosted leaves—words fail.—SOMERS.

“MOUNTAIN” CHRYSANTHEMUMS AND OTHER THINGS.

THE Monte Carlo Chrysanthemum Show took place on November 1, on a day of such unusual heat that it was hard to believe it was not the month of August. The arrangement was artistic, but perhaps not so beautiful as last year. The feature of the show was the cleverly grown “standards” of Chrysanthemums, most wonderful examples of careful culture, but as no names were attached to the plants one is at a loss to describe them. The little Japanese Mountain Chrysanthemums (single) in various colours made effective edgings and neat beds. They are a decided acquisition, but need rather late propagation to keep them sufficiently dwarf. One variety, rather blue lilac in colour, is quite an example of vegetable mimicry; it is so like a dwarf Aster. The tall and well grown specimens of *Phoenix Robelini* made one long to see more of such a lovely decorative plant; few gardeners can have any idea of its beauty. Norimes are, I am glad to say, finding their way down to these coasts at last, but to do them justice it is best to grow them in pots and rest them in the shade all summer. The freedom with which they flower is very encouraging and the variety in colouring and sequence of their time in blooming is gradually increasing. The Manselli and Bowdeni hybrids, moreover, bloom with their young foliage, while the Pothergillii strains are both earlier in flower and leafless when they do bloom, so it is to these two hybrids or strains that we must look. In capable cultivators’ hands they should be very valuable in late autumn. The Tree *Salvia*, *S. frutescens*, is a splendid mass of colour just now, its branches weighed down by the weight of the clusters of smallish scarlet flowers and the Tree *Dahlia*, *D. imperialis*, with its tall nodding sprays of lily-like flowers, contrasts admirably with it. There are few things that cannot be grown to perfection in English gardens, but this is one of them. That fine autumn Snowdrop, *Galanthus byzantinus*, is already shewing a flower or two

despite the unusual heat and severe drought. It must have a very different constitution to the average Snowdrop. It is a fine thing, and seedlings from it vary considerably in earliness and size of flowers, but keep the robust constitution of their parent. We shall, I hope, hear more of it.—EDWARD H. WOODALL.

CALCEOLARIA POLYRHIZA.

MOST folks look upon *Calceolaria polyrhiza* as a kind of “freak of nature” because of the curious shape of its flowers, which are not quite in accord with those of the gorgeous *Calceolarias* of the conservatory or the equally shapely ones of those of the bed in the garden. But the lover of alpinas appreciates these yellow, spotted blooms and the plant, as a whole, because it is a curiously pretty plant which is hardy and can be planted in his rock garden with every prospect of success. It comes from Chili, I believe, and one who travelled extensively there told me how plentiful it was in many parts of the country. It has proved a good grower here in Dumfries and can hold its own and more in the rock garden or in the

THE QUAIN CALCEOLARIA POLYRHIZA.

dryish parts of the bog. It runs about too freely for the comfort of some of its neighbours, but is not happy when confined to a limited space. In a dry place I have seen it flag and suffer in long periods of drought and have felt constrained to give it a soaking of water to make it look happy again. It flowers in July and August.—S. ARNOT.

BERBERIS BERRIES.

RECENT importations and the multitude of hybrids arising therefrom have endowed us with a wealth of berries of which advantage is being taken in our gardens. The fruit is often of more consequence than the flower. I am writing this note to ask if anyone has attempted to use any of them in a culinary way? Some of the *Cydonias* make excellent jelly and fine flavouring for apple tarts—Mauli, in my opinion, being an easy first. Once upon a time the *Barberry*—I presume the Common *Barberry*, *Berberis vulgaris*—was used as a preserve or candied. Hazlitt in his “Old Cookery Books” says it came into favour about the beginning of the eighteenth century. I think he might have fixed an earlier date. I have a small book by an unknown author entitled “A Closet for Ladies and Gentlemen” and dated 1618, in which there is a recipe “To preserve Barberries.” Then nearly eighty years later in “The True Way of Preserving and Candyng and Making Several Sorts of Sweet-Meats” there

are two. One is “To preserve Barberries” and the other is “To make Consarve of Barberries.” This book, the Epistle Dedicatory tells us, is also for “Ladies and Gentlewomen.” The actual date of my copy is 1695. Later still, in 1744, in a rare book, “Adam’s Luxury and Eve’s Cookery,” we again find how “To preserve Barberries.” What’s what in the cookery of her time we may be sure to find recorded by Mrs. Raffold in her famous book, “The Experienced English Housekeeper” (1769), which book seems to suggest that there were more kinds than one which it was possible to use. On page 206 recipes are given for preserving Barberries in bunches and also for their use in tarts. Each one says “Female Barberries” must be used. What does this mean? Are not all the Barberries hermaphrodites? Anyhow it suggested to me the possibility of variation in the flavour of the berries of the different species. On account of my bushes being young I have at present but three different kinds to try, yet I found that, although *Wilsona* and *polyantha* were simply acid, subcaulialata had a delightful aroma. Half of the scanty crop was consumed by birds in a half-ripened state, so willy-nilly, to save the few that remained, they were gathered and made into jelly. Their delicious aroma had vanished (possibly because they were but partly ripe), and the result was something so like gooseberry jelly as to be indistinguishable if one ate it without knowing what it was. It would be of interest to hear of the experiences of others who have made jellies or preserves of *Berberis* berries and who have tried them themselves or who have done what Sir Herbert Maxwell suggests (see his article in the last R.H.S. Journal) primitive men did when they wanted to know what a fruit was like—given some to their poor relations to try!—JOSEPH JACOB.

THE GENTIANELLA.

I WAS much interested in the points raised by Mr. Ingwersen (page 501) with regard to the difficulty in flowering this lovely Gentian experienced by numbers of people who are able to grow other members of the family successfully. His suggestion that its well-being may possibly be dependent upon bacteria is ingenious, but if he meant this to be taken literally surely the theory will not “hold water.” There are not a great number of plants which derive benefit directly from bacteria, those belonging to the Natural Order Leguminosæ being notable exceptions. If, on the other hand, he meant indirectly benefited by bacteria, surely this may be said of every plant in our gardens. My experience has been that this Gentian will flower well in a soil rich in humus with a firm and moist rooting medium. I have known it to grow well and flower freely as an edging in the kitchen garden, where the soil was particularly rich in humus, and refuse to flower in any other part of that garden. Now, I think I am right in saying, the more humus contained in the soil the greater the number of bacteria. If this is so, of course Mr. Ingwersen is right in his theory that the Gentianella is dependent upon bacteria for its welfare, but not more so than other plants, and only indirectly. With respect to the nomenclature query, Mr. Ingwersen is able to speak with more authority than many, being intimate with this beautiful family in its native haunts. I have always held the opinion that it is a “lowland form” of *G. excoisa*, not in the accepted meaning of that term, but a form which has been evolved from generations of garden culture. Possibly the present-day plants are all derived from one planted, say, a hundred years ago and have no affinity with any native form in the Alps.—C. S. G.

EARLY-FLOWERING CHRYSANTHEMUMS

Trials at Wisley.

A VERY useful and interesting trial of early-flowering Chrysanthemums was carried out during the past season at Wisley under the auspices of the Royal Horticultural Society. The manner in which the trial was conducted was most satisfactory, and much credit is due to those personally responsible for all that was done in connexion therewith. It is unfortunate that the weather during the growing period was so abnormal, as this fact is responsible for many curious results which were never anticipated when the trial was in contemplation. Instead of the plants being at their best during the month of September, it was not until the beginning of the second week of October that a sufficient number of plants were in flower to justify one in making an inspection of the trial. A second inspection was made a fortnight later, when quite a large proportion of the plants were in full blossom or had concluded their display. Even at this late date there were many well known sorts that had not come into flower, and probably would never be seen in flower during the current season owing to the interference of frost.

That such a trial was necessary cannot be questioned. Many members of the Society are keenly interested in the early-flowering garden Chrysanthemums, and would be pleased to learn what are the better and more reliable sorts for embellishing their gardens during the autumn months. The awards made by those who adjudicated upon this trial should be followed with more than ordinary interest, as the selected varieties possessed points of merit above the majority and were generally free-flowering plants, possessing a good garden habit of growth. Most of the awards were made in favour of plants producing flowers of warm colours, such as yellow, orange, bronze, apricot, crimson, chestnut and other intermediate tones of these colours. There were some very excellent white sorts and just a few varieties yielding flowers of claret, purple and other closely allied colours, for which there is an occasional demand and for which some persons have a partiality.

A few single-flowered sorts were favoured with recognition, and a small selection of pompon varieties, several of them very old, were included in the list of those selected for award.

Altogether there were about 450 stocks sent in for trial, but several of these were sent in by as many as four firms, and there were instances where as many as six stocks were sent in of one variety. More often, however, there were two stocks shewn of one variety. There were in all about 115 varieties, but many of these were classified by the Committee as synonymous or too much alike. There were instances where one variety appeared under three distinct names. It is of great value to have this cleared up, and the public will doubtless take full advantage of it.

Three plants of each variety were grown in the trial, and the condition of the plants during the usual period of flowering was an excellent testimony to the care bestowed upon them during the past extraordinary season.

One fact that impressed itself upon the mind of the writer on the occasion of both visits was that there was room for considerable improvement in these early-flowering garden Chrysanthemums. This section has not made the progress that is so noticeable in the early-flowering market varieties. Leading market growers have been particularly careful for some years past as to the

varieties which they cultivate so largely, usually as disbudded plants, and they have certainly produced many very beautiful kinds. Few raisers have devoted their attention to the early-flowering garden sorts, and, as a consequence, present-day lists contain a large number of mediocre sorts that are grown by many, not necessarily for their beauty, but because there are no better varieties to grow. In the writer's opinion what are needed to-day are more sorts possessing the branching characteristics and constitution of the Mme. Marie Massé family of the early Chrysanthemums with the beautiful form and character of the more recently introduced

Normandie.—A well known free-flowering dainty sort producing pink flowers of a distinct colour.

Freda.—This is a new mauve pink flower, the plant being about 2ft. high.

Mme. Marie Massé.—Still one of the best. Extremely free-flowering and bushy, with a good constitution; colour, mauve pink.

Claret.—For its striking bright claret colour this free-flowering sort has a value; 2½ft.

Jamie.—This was a plant bearing striking purple flowers.

Lichfield Purple.—This plant is fully 3ft. high and bears, in the greatest profusion, blossoms of a striking purple colouring—beautiful in the autumn sun.

Ralph Curtis.—Plants of White Massé, Mrs. Bailey and Tuckswold Early were similar in every way to the variety under notice, and the three sorts were too much alike to be regarded as

THE BEAUTIFUL ANEMONE-FLOWERED CHRYSANTHEMUM SNOW QUEEN.

This attracted considerable attention at the National Chrysanthemum Society's recent Show.

Almirante and *Red Almirante* (syn. *Alcalde*). These latter varieties are among the best of present-day early-flowering sorts, which for the garden and cut-flower uses are unsurpassed.

The following are the awards made by the Committee at the Wisley trial.

AWARDS OF MERIT.

Candida (also known as *Sanctity* and *Excelsior*), a pure white sort, useful in sprays (undisbudded), beautiful when disbudded.

Framfield Early White (syn. *Framfield White*).—A sturdy-growing plant, pure white.

Roi des Blancs.—A small-flowered pure white sort of very Japanese type especially useful for cut flowers; 3ft.

September White.—One of the most remarkable pure white sorts in the whole trial. The plant is about 2½ft. high, and is literally smothered with beautiful chaste blossoms.

Silver Lining.—Some plants sent in as *Miss G. K. Thorpe* were similar to the variety under notice. The plant is of slender, wiry growth and the blossoms are of a bluish colour.

Pearl.—A charming dwarf plant bearing pretty pink blossoms.

dissimilar. Colour, creamy white. This is one of the members of the "Massé" family.

Charming.—This is a new sort of a beautiful primrose colour. It is free-flowering and is also good disbudded; 2ft.

Framfield Early Primrose.—Southover Yellow and Willington Early Yellow are regarded by the Committee as synonymous with the variety under notice; pale yellow.

Horace Martin.—Elstob Yellow and Maggie are both bracketed with the first mentioned as synonymous. I question, however, whether the last-mentioned stock was true. Free-flowering and branching; bright yellow. A member of the "Massé" family.

Hollicot Yellow.—Goldfinder and Philip were classified as synonymous with the variety under notice. Stiff, upright habit. Good disbudded or otherwise. Bright orange yellow; 2½ft.

Golden Polly (syn. *Florrie Wilkinson*). A beautiful orange yellow sort. Rather slender growth, dwarf.

Golden Almirante (syn. *Vinstone Bronze*).—A beautiful orange yellow form of the "Almirante" family, and, as such, worthy of attention.

E. Miller.—A most attractive orange flower worthy of special notice.

Polly.—This variety when well grown is most attractive; colour, bronzy orange, passing to yellow.

Verona.—A charming little flower of the brightest orange terra-cotta colour. Beautiful in sprays, and dwarf.

Phania.—A somewhat unique sort, bearing pretty little flowers with twisted florets. The latest flowers are almost scarlet, earlier flowers, rich terra-cotta.

Wells' Scarlet.—This is a small crimson-scarlet flower with gold reverse to the florets; 2½ft.

Mrs. Jack Pearson.—Regarded by many as one of the very best sorts in the trial, this is a perpetual-flowering plant, beginning in August and continuing until November (under protection). Colour, bright bronze; 3ft.

Hollicot Beauty.—September Glory and Shirley Conquest were regarded as synonymous with this variety; colour, bronze.

Bronze Goacher.—The variety Mrs. J. Fielding as sent to the trial by some firms is synonymous with this variety. This was another of the better plants in the trial, flowering in profusion; colour, bronze.

Crimson Polly.—Abercorn Beauty as sent to the trial was similar to the sort under notice, but really it is quite distinct from that variety; colour, deep chestnut crimson; dwarf.

Crimson Marie Massé.—Another member of the "Massé" family; crimson bronze. A most reliable sort.

Mrs. J. Fielding (true).—One of the very best sorts in the trial. Very free, good habit and constitution; bronzy chestnut.

Ernest Ballet.—A well known October-flowering variety; colour, red; 3ft.

Fidelity.—Another free-flowering, branching plant; colour, chestnut crimson. Pretty Japanese flower.

Ethel Blades.—A small-flowered decorative sort, useful in sprays for cut flowers; colour, chestnut crimson.

Alcalde (syn. Red Almirante).—One of the brightest flowers of the whole series and one of the best of the later introductions. Colour, brilliant chestnut crimson; 2½ft.

Almirante.—The original of many varieties, all sports from the parent plant. Ideal as a cut flower; bright orange bronze; 2½ft.

Goacher's Crimson.—Still a very popular garden variety. Flowers of good form; colour, deep rich crimson; 2½ft.

Dick Barnes.—An English-raised seedling, dwarf and bushy; colour, a somewhat unique burgundy crimson.

Mrs. W. Sydenham. This is a plant with a rather spare habit; 2ft.; colour, rich crimson.

Badia Ferrer.—An attractive plant seen for the first time in this trial; colour, rosy crimson, yellow reverse; 2ft.

POMPONS.

Flora.—A very old bright yellow Pompon, begins to flower in August and continues to bloom for a long time. Dwarf and bushy.

Orange Pet.—Another useful Pompon, rather larger than most others. Useful as a cut flower. Bright terra-cotta.

Little Bob.—One of the oldest of the Pompon sorts. This variety is also known under the name of Scarlet Gem. Slender stems; colour, crimson-brown; small flowers in sprays.

SINGLES.

J. Woolman.—A charming little plant bearing pretty pink and white single flowers with a yellow disc.

Golden Firebrand.—A useful garden Single of an orange yellow colour.

Midnight Sun.—This is another useful single-flowered sort for garden decoration; colour, terra-cotta; 2ft.

Firebrand.—A pretty chestnut crimson Single producing excellent sprays for cut flowers; 3ft.

Ruby.—Another useful garden Single; colour, deep crimson; 2ft.

Garnet.—Still another attractive Single for the garden; colour, crimson; 2ft.

Chickadee.—A comparatively new Single of a brilliant crimson colour; 3ft.

Mrs. S. Smith.—This is a new Single of beautiful form; colour, reddish crimson; 2ft.

Glorious.—A new Single with three rows of florets; colour, crimson; 3ft.

Laplow White.—The most beautiful of all the early Singles; pure white; extremely free-flowering; 2½ft.

The following varieties were highly commended: *Blanche du Poitou*, white; *Miss G. K. Thorpe*, white; *Bijou*, pink, charming dwarf plants; *Provence*, pink; *Bonquet Rose*, bright rose; *Eden*, rosy mauve; *Rubis*, rose; *R. Pemberton*, rosy purple; *Cream Perrier*, creamy yellow; *Chatillon*, pale yellow; *Golden Diana*, yellow; *Miss Ethel Harvey*, yellow; *Leslie*, bright yellow; *Carrie*, yellow; *Guinea Gold*, orange yellow; *Harry Thorpe*, orange yellow; *Nina Blich*, chestnut bronze; *Golden Goacher*, golden bronze; *Bronze Provence*, bronze; *No. 1 Bronze*, bronze; *President Maugy*, chestnut; *Red Cross*, chestnut crimson; *L'Argenteillaise*, chestnut crimson; and *Fleuve Rouge*, chestnut crimson.

Pompon Varieties.—*Mr. Selby*, blush; *Gladys Gray*, yellow; *Craigmillar*, rich yellow; *Mignon*, soft canary yellow; and *Perry's Seedling*, bronze.

Single Varieties.—*Rose Perfection*, mauve pink; *Mizpah*, amaranth; *Fairy*, pale mauve pink;

Rosamund Hall, pale rose pink; *Rosea*, deep rose pink; *Canary*, yellow; and *Shrapnel*, rich terra-cotta. D. B. CRANE.

During the progress of the extensive trial of Early-flowering Chrysanthemums just concluding at Wisley, members of the Garden Committee were deputed to select the twelve varieties which, in their opinion at the time they saw the trials (when most of the varieties were in full bloom), were the most desirable for growing in the majority of gardens. Their choice fell upon the following:—

White.—SEPTEMBER WHITE and CANDIDA (also sent as Sanctity and Excelsior).

Pale Yellow.—FRAMFIELD EARLY PRIMROSE (also sent as Southover Yellow and Willington Early Yellow).

Yellow.—HOLLICOT YELLOW (also sent as Goldfinder and Philip), and HORACE MARTIN (also sent as Elstob Yellow and Maggie).

Orange Yellow.—GOLDEN ALMIRANTE (also sent as Vinstone Bronze).

Bronze.—MRS. JACK PEARSON and BRONZE GOACHER.

Chestnut.—ALMIRANTE.

Chestnut Crimson.—RED ALMIRANTE (also sent as Alcalde).

Pink.—NORMANDY.

Purple.—LICHFIELD PURPLE.

[The above selection is interesting but scarcely convincing in some particulars. Few practical growers will consider Bronze Goacher, for instance, as better than say, Harrie, while throughout there appears to be a disposition to select large-flowered varieties, whereas for border decoration the sorts with smaller blossoms are often more satisfactory. It must be an unusual stock of Elstob Yellow, too, which is synonymous with Horace Martin.—ED.]

THE PROPAGATION OF CHRYSANTHEMUMS

Cuttings should be rooted from December to March if a prolonged display of blossom is to be obtained a year hence.

ACTUALLY, long before the flowers of one year have faded or been gathered the stock of young plants for the next year must be propagated, which shews that the successful cultivator must look well ahead. There are several reasons why early propagation is advisable in many gardens. Naturally, late-flowering varieties require a long season of growth; the large pots in which the old specimens grew take up much valuable space, their sucker cuttings do not when they are placed in a propagating frame. The following are some of the late-flowering sorts to root first: *Mrs. Gilbert Drabble*, white; *W. Rigby*, a yellow sport from the latter; *Victory*, a large white when early crown buds are secured; *Queen Mary*, white and waxy; *Princess Mary*, a yellow sport from the last; *Majestic*, golden amber; *Louisa Pockett*, a large reflexing white; *Mrs. Charles Davis*, also a large refined white flower; *Mrs. R. C. Pulling*, lemon yellow; and *Mrs. M. Sargent*, white, shaded or suffused green. These are grown chiefly to bear large exhibition blooms, and the cuttings should be rooted singly in tiny pots. The propagating frame should be placed on the greenhouse stage or a similar position in a low-rooted pit where the temperature ranges from 48° to 60°. A very mild bottom-heat would hasten root formation, but it is not absolutely necessary, as roots will form in due course in a cold structure. Frost will not kill the cuttings, but it retards root action, so it is advisable to keep them safe from frost at every stage. My ideal propagating

frame is one runs high at the back, 12ins. at the front, containing a bed of coconut fibre 4ins. deep in which to plunge the small pots to their rims; this helps to conserve moisture evenly, hastens root formation, and with it the cuttings at this season rarely need watering after the "settling in" at the time the cuttings are inserted. My ideal compost is made up as follows: Old fibrous loam (a year old or so), two parts; sweet leaf-soil, one part; pounded bricks—old ones—and old mortar rubble, one part. The sand used should be very coarse and clean and dry, one pinch being dropped in the hole made in the compost so that it will rest at the base of the cutting.

Under rather cool conditions these early cuttings require five weeks in which to root; four weeks when artificial heat is used. Insert stocky sucker cuttings and keep them sturdy by removing them from the frame to more open quarters directly they are rooted; but full exposure to air should be gradually brought about by ventilating them liberally in another temporary frame for one week.

The second batch of cuttings should be dealt with about the first week in January, and these will root in one month's time or, with the aid of gentle bottom-heat, in three weeks. The following are a few of the good sorts to insert: *Dawn of Day*, orange and bronze; *Edith Cavell*, orange, flushed red; *Golden Champion*, golden bronze; *Mrs. John Balmer*, red and gold; *Mrs. Charles Curtis*, white, flushed mauve; *Mrs. A. Davis*, pink; *Mrs. G. Monro*, Jun., rich crimson; *Mrs. J. Gibson*, pink; *Mrs. Peter Murray*, rich purple;

Mrs. Spencer Chichester, primrose yellow; Rose Day, lovely pink; and Viscount Chinda, a magnificent yellow.

At this season, also, batches of cuttings of the autumn and winter decorative varieties should be rooted, followed in another month's time by the single-flowered. The very earliest border

and indoor sorts should finish the work of propagation by about the end of March.

The propagation of the later batches of cuttings may be carried out in boxes in cold frames, transferring the rooted plants to other boxes or beds in cold frames prior to planting them in their flowering quarters.

GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Winter Spinach.—This crop should be examined from time to time and any dead or decaying leaves removed, while if the soil is dry enough the hoe should be used. A light dusting of soot will be beneficial, and at the same time it will check the slugs from eating the leaves.

The Warm Border.—In many kitchen gardens there is a warm, sheltered border, which will be found very useful a few months hence for early crops. In the meantime it should be thoroughly dug or trenched, at the same time incorporating a liberal quantity of manure. This border requires doing well, and we always save all the old soil from the potting bench, which is very useful for a border of this description. It makes the soil light, and the surface dries more quickly in the early spring.

Salsafy.—If not already done, the roots may be lifted and stored in sand or ashes. A cool shed should be chosen for storing the roots, and it should be freely ventilated on all possible occasions.

Preparing Soil.—To obtain vegetables of good quality the soil should be well tilled, and although manure is essential, in all probability deep cultivation is the secret of success. At this season deep digging and trenching should be proceeded with, and if the garden is divided into four portions, one section could be trenched each year. It is not such a laborious task as many imagine, and even the amateur would soon make considerable headway in a few Saturday afternoons. Unless the soil is of a loamy nature 2ft. or 3ft. deep, I prefer to leave a cold, heavy subsoil at the bottom, merely turning over the lower spit, incorporating long manure and any light soil that may be at hand. This will not only improve the root-run, but assist the drainage, and the effect of a dry hot summer will not be so disastrous. A garden which is dug one spit deep every year eventually forms a hard pan, which restricts the roots and prevents moisture from rising or entering the soil. Deep cultivation should be the rule and not the exception.

The Flower Garden.

Sloping Banks.—Where there is a fair depth of soil it is not difficult to furnish banks and make them quite attractive. Many of the Rambler Roses will succeed, especially those of the Wichuraiana type, while if shrubs are needed that will bear cutting back, then the Common Laurel, Aucuba and Eonymus may be chosen. For dry, stony positions Common Furze is excellent, while for more or less shady places the St. John's Wort, Ivy and Periwinkle will be available.

Specimen Trees.—Conifers should be examined and all secondary leaders removed, while deciduous trees should be pruned, where necessary, to enable them to develop into well balanced specimens. In this district Ivy is a pest, and it becomes a necessity periodically to go round the trees in the pleasure grounds and woodland and cut the growths of the Ivy. If left for several years it makes considerable headway.

Michaelmas Daisies.—These are quite a special feature in many gardens, a border or several beds being devoted to their culture. Frequent division is needed, and the young pieces on the outside of the clumps should be chosen when replanting. The soil should be dug deeply and given a liberal dressing of manure. No attempt is made to furnish a full list of these delightful plants, but the following have given satisfaction this autumn: Climax (one of the best), Brussels, King of the Belgians, Blue Gem, Robinson V.C., Brightest and Best and Amellus King George.

Spartium junceum.—This is an excellent plant for arranging in bold clumps or patches in the wild garden or shrubbery. It produces

numerous golden yellow flowers in July and August when flowering shrubs are past their best. It is readily raised from seeds.

The Hardy Fruit Garden.

Gooseberries.—These delicious fruits are usually met with in bush form, but they are also well adapted for growing as cordons, from which some excellent fruit can be produced. For small gardens a larger number of trees could be grown, and with a suitable selection of varieties and positions, the supply of ripe fruit could be prolonged. Moreover, the berries are easily gathered and protection from birds rendered less difficult. Many firms offer trees trained as cordons.

Quince.—This is a late autumn fruit highly prized by some for cooking and preserving, and as a rule one or two trees are sufficient. The pear-shaped variety is perhaps the best for general use; The Portugal is also a good kind, but does not ripen its fruits so well in a cold wet season. The Quince enjoys a somewhat moist position, but it will succeed almost anywhere. Thin out the shoots occasionally and cut back any long growths to six or eight buds.

Fruits Under Glass.

Planting Vines.—Where it is intended to replace old Vines the work should be proceeded with. When the old rods are removed the soil should also be taken out and a fresh start made. Good drainage is essential, and the best fibrous loam should be employed for the border. This should be made quite firm, and only half of the border need be made at the present time. No artificial manure will be needed, but half to three-quarters of a hundred-weight of quarter-inch bones to every cartload of loam may be added. A barrowload or two of broken bricks and old mortar rubble is also desirable.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Broccoli.—Unless precautions are taken the crop in the colder districts is not infrequently either partially or totally destroyed by frost. By heeling the plants over to the north the crop stands a much better chance of escaping injury. Practical gardeners know well the damage often done to more or less tender plants by the morning sun playing on them after a night's frost. To heel them over take out some soil with the spade immediately behind the stem, then push the plant over, place the excavated soil on the south side of the plant and with the foot tread the soil firm.

Kohl-Rabi.—The few who grow this vegetable should draw some earth over the bulbs, just leaving the foliage exposed. This will protect the bulbs from frost and will also help to keep them tender; when exposed, they tend to harden.

Brussels Sprouts.—Any late batches should be gone over, all decayed leaves should be collected and transferred to the heap for vegetable mould. If the leaves are rather abundant, some of them—the green leaves—should also be removed, giving the sprouts a better chance of developing by enjoying an increase of light and air. Early batches when stripped should be cleared away so that the ground may be manured and dug.

Fruits Under Glass.

The Late Peach-House should be thoroughly cleaned and the border top-dressed. The ventilators should be left open night and day except in severe weather.

Late Grapes, whether hanging on the Vines or stored elsewhere, should be frequently examined and any decaying berries promptly removed, or they will infect others.

The Early Vinery.—If ripe fruit is wanted at the beginning of summer, the house should now be shut up, and, at the end of ten days or so, sufficient fire-heat should be applied to maintain a night temperature of between 45° and 50°. It is understood that the border was attended to as regards water when the house was cleaned and the border top-dressed, but if that was not the case attention should be given to it now.

The Flower Garden.

Christmas Roses.—This is the month in which the true Christmas Rose, *Helleborus niger*, flowers, and the plants should be protected by means of a frame, handlights or sheets of glass supported by metal standards furnished with clips to keep the glass in position. This protection keeps the blooms clean.

Carnations.—Autumn-planted layers are apt to get slackened by frost, so should therefore be examined after a spell of frost, and if damage has been done they should be made firm. Layers in pots in frames should receive abundance of fresh air, and a close watch should be kept that mice do not attack them.

General Work.—Advantage should be taken of this quiet month to do some planning as regards planting schemes for next summer, so that one may form an approximate estimate as to the quantity of different plants to be propagated by cuttings in the spring, also the kinds and quantities of seeds which it will be necessary to order next month. Instead of trusting to memory, it is advisable to have a record of one's intentions either in the form of a marked plan or simply in notes, it being understood that such conclusions are subject to modification.

The Pleasure Grounds.

Laburnums seldom develop any length of bole, but make a break within 1ft. or 2ft. of the ground. As the trees advance in years they often split at this first break. When this occurs they should be banded with an iron band, the band being tightened up with a bolt and nut. The fissure should then be filled up and nicely finished off with pitch, which can be painted in an inconspicuous shade.

Lilacs when not regularly attended to as regards pruning generally develop two or three extra strong branches which overtop the general growth. When taking these in hand they should be sawn off about halfway down the bush, so that the growths which will break away from the cut portions will come into line with the rest of the growth.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Lapagerias.—Now is a good time to plant out young plants from pots. Although they may be successfully grown in large tubs, they are only seen at their best when they are planted out in a cool house. As they enjoy cool and moist atmospheric conditions, they are best placed in a position where they are partially shaded for at least a part of the day. For this reason they are useful for planting in that part of a house which enjoys least sunshine. If planted out in a bed they should have ample drainage, as they run very much underground. It is wise to confine them to a certain space by enclosing a portion of the bed with slates or bricks. If this is not done some of the strongest shoots are sure to come up in unexpected places and thus run the risk of getting damaged. The compost should be in a rough, lumpy condition, consisting of equal portions of good fibrous loam and peat, with enough clean coarse sand and charcoal to keep the whole open and porous. During their growing season Lapagerias require almost daily attention as regards training and regulating the young growths, which are very brittle and easily damaged. As growth is now finished and the foliage hard and matured, this is a good time to give the plants a thorough cleaning; they are subject to attacks by mealy bug and scale insects. When they start growing next year a sharp look-out should be kept for slugs, which are very fond of the young ground shoots.

Tydæas are very useful for furnishing the warm greenhouse during the autumn and winter, and they should be more generally grown for this purpose, as their pretty and quaint markings always attract attention. There are a number of named varieties which, of course, must be grown from the dry rhizomes. These plants are easily raised from seed, and a pinch sown early in the New Year should give all the variety necessary.

On younger stages they are best grown in a cool house in a temperature of about 50° and as they increase in size they should be grown in cooler conditions. During the summer months they may be grown in cold frames, keeping them fairly close and moist and shutting them up early with plenty of sun heat. Grown fairly cool they are much sturdier and stand better when moved to the greenhouse.

Astilbes are very useful for the greenhouse. A japonica and its varieties have long been popular for this purpose. There are now a number of pink and rose-coloured varieties which are largely grown for this purpose. As they are strong-rooting plants it pays to give them fairly large-sized pots, according to the size of the roots. After potting, they may be stood in cold frames or placed outdoors, plunging the pots to the rim in ashes until such time as it is desired to introduce them to a warm house. A house with an intermediate temperature is best for this purpose. When in full growth they take almost unlimited supplies of water at the root, and it is a good plan to stand them in shallow saucers of water.

Spiraea palmata should be given the same treatment as that advised for *Astilbes*.

Michelia fuscata (syn. *Magnolia fuscata*).—This small evergreen shrub is worth planting out in the cool conservatory, and it succeeds quite well in a mixture of fibrous peat and loam. The small reddish brown flowers are not large or showy, but they are so deliciously fragrant that this plant is always worth a place in the cool greenhouse. It is not long happy under pot cultivation and is best planted out.

Lomatias with their elegant foliage are very useful for the cool conservatory. *L. ferruginea*, with its beautiful pinnate evergreen foliage, makes a splendid specimen when planted out in a cool house. As this plant is more or less hardy in the South and West, it is well suited for planting out in the unheated greenhouse. *L. silaifolia* is a much smaller growing plant with very elegant, finely divided foliage. It makes a pretty pot plant, and also does well planted out in the front of a bed or border in a cool house. This plant is easily propagated by means of cuttings, but *L. ferruginea*, like most Proteaceous plants, is by no means easy to propagate. Cuttings should be selected from the smaller side shoots and inserted in pots containing sandy soil, standing them under a bell-glass in a cool house or cold frame.

Acacia platyptera is very distinct and is now in flower, and on this account is very valuable, as it affords a welcome variety in the greenhouse at this time. This *Acacia* is propagated by means of cuttings during the spring.

Royal Botanic Gardens, Kew.

J. COURTIS.

BOOKS

The Celmisias.—It is a little strange that, while British plant- and seed-collecting expeditions to the wilds of Asia have been so common during recent years, we have in the gardens of Great Britain so poor a representation of the, generally speaking, very beautiful flora of New Zealand. The thought is one which often recurs, but it is brought forward at this moment by reading a very interesting little book on the *Celmisias* and *Olearias** by Sir George Fenwick and James Speden. Quite a number of *Celmisias* are illustrated in half-tone, and it is evident that the smaller species are among the most beautiful of alpine plants—exquisite in foliage, beautiful in flower. Those which would not flourish outdoors with us would be splendid for the alpine house. The larger growers are equally beautiful in their way and there is a good selection, thirty-one species being described in the book, while a large number of natural varieties are also in existence. Botanically, the *Celmisias* seem to be practically herbaceous forms of the genus *Olearia*, of which twenty-one species are described by Mr. Speden. Some of these are tender in less sheltered places in New Zealand, so that they will be no use outdoors in Britain, but such finds as *O. macrodonta*,

ilicifolia and *nummularifolia* and the Tasmanian *O. stellata* undoubtedly withstand our winters better as they become acclimatised.

The Orchids of Europe.—M. Correvo's new edition of the "Album des Orchidées d'Europe" should be in the possession of all lovers of the remarkable and, generally speaking, beautiful terrestrial Orchids. In the text, fairly copious references are made to hardly non-European terrestrial Orchids, but the detailed descriptions, of course, and the splendid plates deal only with the European species. Of the forty-three British species enumerated in "Druce," forty-two are illustrated in this work—*Spiranthes Romanzoffiana* in black and white, the rest in colour—the exception being *Habenaria* (*Orchis*) *intacta*. *Spiranthes aestivalis* is, however, inadvertently labelled *Serapias aestivalis* on the plate and in the Index to the plates, and those who procure the book will be well advised to make the corrections. The descriptions of the various species are excellent, and the cultural directions (where the species are amenable to cultivation) clear and simple. M. Correvo, not without reason doubtless, labels all the saprophytic and parasitic species as impossible of cultivation, but one would think that they might be naturalised on their host plants from seed. The author seems to have found English names for all the species illustrated, but many of them are not exactly happy and some affect the risible faculties. The gem is, perhaps, *Serapias longipetala* (*Serapie à long labelle*), of which the English equivalent is supposed to be "Long-labelled *Serapias*." We can, I think, safely call that a *wrong-labelled Serapias*!

It has often seemed regrettable that the cultivation of hardy Orchids has not extended farther in England, and it is, in a way, consoling to find that M. Correvo seems to think that we have done more than our part in this country in the way of their successful cultivation. He mentions the Rev. Wolley Dod and Mr. G. F. Wilson as veritable pioneers, while he considers Mr. W. H. St. Quintin's collection at Scampston Hall a model arduous of imitation. It is pleasant to lay "this flattering unction to our souls," but with a climate more suitable than most for the cultivation of the generality of species, it is something of a reproach that more has not already been done. Will not more hardy plantsmen be up and doing with these most interesting plants? A necessary preliminary, however, must be the possession of this admirable monograph. R. V. G. W.

* "Album des Orchidées d'Europe," par H. Correvo. Published by the Author at "Floraire," Chêne-Bourg, Geneva. Price 25 francs.

Garden Ornaments.—These are one of the most expensive items which help to adorn the garden, therefore care should be taken to use them to the best advantage. They should serve a purpose as well as be ornamental. In a formal garden statues are often used with the idea of breaking up the formality, and yet if placed correctly they are quite in harmony with their surroundings. Sundials make good objectives for the terminations of paths and serve well as centrepieces where two or more paths cross, providing the crossing is in the open. Bird baths are sometimes used instead of sundials, and are far more interesting near the house, where a good view can be obtained of the birds' appreciation of the facilities for bathing. Too many ornaments in a garden spoil everything else; they are like specimen trees or shrubs, to be admired singularly and not in a bunch. Garden ornaments are, perhaps, not a necessity, but if used in the right place they help to give form to the garden.

Some Beautiful Late-flowering Heaths.—The Dorset Heath, *Erica ciliaris*, does not seem

to be as widely grown as it deserves. This is the more strange when one realises that it is practically the only *Erica* species of lowly habit which is in full flower during the later autumn and right on to winter. The singular attractiveness of *E. ciliaris* consists not only of its fine spikes (2ins. to pins. in length) of large, rosy lilac flowers, but the trailing masses of foliage in a soft glaucous green are very delightful. This species may be a little tender compared with *E. cinerea* and others, but it is quite hardy enough for most places, and will thrive in any lime-free loam that is freely drained. The blossoms in the form known as *E. c. Maewana* are even larger than those of the type and a bright rosy crimson, the foliage being greener and the branches rather more upright in habit. Closely resembling *E. ciliaris* is *E. Watsoni*, a natural *ciliaris* × *Tetralix* hybrid. This is also a good late bloomer, and while the grey-green, hairy foliage comes near to that of the Dorset Heath, the rosy lilac blossoms appear in rather a flatter terminal head suggestive of its other parent.

Veronica Lyallii.—This is a charming little shrublet of a few inches, with small, almost round, glossy green leaves very slightly notched at the margins. About midsummer and thence to autumn it maintains a succession of pretty, white, pink-veined flowers which are borne on elegant, branching sprays to a height of about 6ins. The habit of growth is almost prostrate, the tiny branches taking root as they progress. *V. Lyallii* is quite hardy in most places, given a well drained soil. A position that is screened from the noonday sun appears to be the most suitable. There are, doubtless several forms of *V. Lyallii*, as there are of its near ally *V. Catarracte*, and the latter is, as often as not, seen bearing the name that rightly belongs to the former. *V. Catarracte*, however, is considerably larger in all its parts, and more erect in habit. A notable distinction may be observed in the leaves, which in the last mentioned are not merely much larger, but narrower, more pointed and sharply indented. Both of these *Veronicas* are ideal shrubs for the rock garden.

An All-Season Flower.—For persistent blooming from spring to winter *Erysimum* (*Cheiranthus*) *linifolium* has no rivals among its kind. In addition to this admirable quality it is a perennial of singular charm of habit, and the beautiful cool lilac blossoms never fail to arrest attention. *E. linifolium* comes from Portugal, and it is one of those easy-tempered plants that will do at the margins of the border, in the rock garden or on a dry wall with equal success. It will, moreover, often adapt itself to the conditions in which it is placed by growing tall or short, large and bushy, or squat and clinging, yet it rarely fails to bloom continuously and to produce a sufficiency of self-sown seedlings which come true to type. *E. linifolium* might be described as a lax-habited bush about 1ft. in height and perhaps 2ft. in width, but in poor, thin soil, in which it does so well, it may not attain more than half those dimensions. Though delighting in sun, it is not averse to some shade, and if the seedlings are planted young they will prosper in the chink of the driest, most sun-baked rock.

Now Made in
Two Sizes.

NEW SPRAYING MACHINES LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete without a Sprayer, in fact a Sprayer is absolutely essential to obtain best results. During the War we

supplied a considerable number of our well known Four Oaks Knapsack Sprayers—Rubber Diaphragm type—to the Government, and we have just re-purchased a small quantity back again, which have never been used. They are

made of copper but painted Service grey colour. They have various special additions to the ordinary machines, and the price to-day would be £5 each. We guarantee them to be in perfect working order as new. We will send one machine carefully packed, carriage paid, on receipt of 50/-, but cash must accompany all orders. We would supply 2 machines for 90/-, carriage paid.

Please mention this Paper when ordering.

It's the same with Paint.

THERE'S many a soap that, after a fashion, will cleanse your hands of grit and grease; but most of them jib at paint.

Kit is absolutely in its element with a job like paint or varnish or tar. Just a little water, an easy rub-rub-rub, and in a trice the hands are clean.

Kit is a Speed Soap from the word "Go!" The tin is easy to pack and pull out again, and the special lid lifts off at once. And, if you're in a tearing hurry, you can easily use it without water!

6d PER TIN.

LEVER BROTHERS LIMITED PORT SUNLIGHT

A FEW GOOD THINGS FOR PRESENT PLANTING AND POTTING.

FOR GREENHOUSE.

FERNS. Bright bushy young plants including *Nephrolepis*, *Aspleniums*, *Cyrtomiums*, *Adiantums*, *Pteris*, etc. ready for pots, 2/6 doz., ex 24in. pots, 4/6 doz. *Asparagus Plumosus* and *Sprengerii*, transplants, 2/6 doz. ex pots, 4/6 doz.

CYCLAMEN. Strong vigorous young plants, ready for pots, 2/6 doz. Giant white, salmon, crimson, scarlet and mixed. A very choice and superior strain.

GERANIUMS. Well rooted sturdy plants for winter flowering, in scarlet, pink, salmon, white, 3/6 doz. Finest varieties.

PRIMULAS. *Obconica gigantea*. Our strain of these wonderfully floriferous plants is particularly noted for its very varied shades of colour and large size of bloom. Strong plants, ready for potting, 2/6 doz. *Kewensis*, winter flowering, bright gold, a little zebra, 2/6 doz.

FOR OUTSIDE PLANTING.

ALPINE PLANTS. In great variety, including *Saxifragas*, *Sedums*, *Veronicas*, *Campanulas*, *Thymus*, *Silene*, *Dianthus*, etc., all ex pots, 6/- doz. Collections of 12's, 25's or 50's, every plant different if desired, at 6/- 12/24.

ALLWOODII. Peggy, Eleanor, Joyce, Maud, Marian, Joan, Rufus, Betty, ex pots, strong plants, 4/- doz.

AQUILEGIAS. Scott Elliott's Long-spurred, a charming strain, strong plants, 2/6 doz. Chrysanthemum, a pale yellow variety, 2/6 doz.

AURICULAS. A very choice strain with a wonderful range of colours, 2/6 doz.

BELLIS (Daisies). Rob Roy (crimson), Alice (pink), Dresden China (miniature pink), Minima (white, the smallest of the Daisies), Jolly little plants to meet on a fine spring morning, 2/6 doz.

LITHOSPERMUM. Heavenly Blue, a plant which has captured a bit of the summer sky. Strong plants, 6d. each.

PINKS. Her Majesty, a splendid large fragrant white, 2/6 doz. Mrs. Sinkins Improved, much larger than the old type, 2/6 doz. Glory, dpc. crimson with picotee edge of ruby, 6/- doz. Ingham, a silky soft pink shade very charming, 6/- doz. Crimson Beller, effective, 2/6 doz.

POLYANTHUS. Large-flowered, a very superior strain, strong plants, 2/- doz. Primroses, mauve and purple shades, large clumps, 6/- doz. Blue, large plants, 6/- doz.

SAXIFRAGES. Mossy varieties, forming dense tufts of foliage, and producing in April to June pretty spikes of white, rose and crimson flowers, 4/- doz. Encrusted, one of the most charming and varied groups of plants we have, forming neat rosettes of foliage and handsome sprays of bloom, 5/- doz. *Kabschia* section, the latest and choicest of silver Saxifragas, 6/- doz.

THRIFTS. *Leuchanthes*, easy and compact, bright rosy-pink, 2/6 doz. *Cephalotes*, rat and hearty, large-flowered, rose, 3/- doz.

VERONICAS. Prostrata, forms a sapphire sheet close to the ground, 2/6 doz. *Salicornoides*, robust evergreens with white flowers, 6d. each.

Quarter-dozen at dozen rate. Catalogue on request. All Carriage Paid.

Notes from Maidstone.

MASSED ROSES.

The old plan of one bed many varieties has now been largely displaced by the far more effective method of one variety in each bed.

We cannot too highly recommend Golden Emblem for this purpose, the dark foliage making an admirable foil to the large golden yellow flowers.

The Price is 22'6 per dozen.

SUITABLE WALL PLANTS

IT is regrettable that when writing of wall plants one's first thought has still to be of sounding a warning against their abuse. The function of climbers on a house wall should be to adorn, not to conceal. There are, doubtless, exceptions to this rule, since there are houses of a hideousness so peculiar that all we can do with them is to conceal them. This should, however, be a last resort; many structures which look bald and uninteresting as they leave the builder's hands may be made quite seemly by judicious planting. A long, blank wall may be broken up by the use of "pilasters" of *Pyracantha* and other shrubs of similar habit, while the *Wistaria* seems to have been "designed" to replace missing cornices and string-courses.

People are always inveighing against Ivy as a destroyer of trees, but it is comparatively seldom that one hears, or sees, it assailed as an obliterator of architecture. Undoubtedly the Ivy is no friend of the forester, yet in the purlieus of the home it may be forgiven for its strangling grip on account of its beauty of leaf and berry. On a house wall, unless most carefully handled, it obliterates what a climber less dense would have emphasised, yet it must be owned that it has its practical uses. It will keep dry a wall which could otherwise be rendered damp-proof only by rebuilding—always provided that the mortar has not already perished badly. The presence of Ivy on partly-ruined buildings of architectural interest is all to the bad, for the penetrating roots quickly dismember the fabric.

Vitis inconstans, best known in gardens as *Ampelopsis Veitchii*, is valuable not only for its brilliant autumn colour, but for the tracery it stretches over ugly stretches of facing bricks—especially the unsightly deep ones seen in the Midland Counties. On really good walls, whether of brick or stone, it is less satisfactory, and it should never be allowed so to smother chimneys and gables that it destroys their apparent form. In short, this, like the Ivy, is a useful, even a beautiful, plant, but one easily misused. *Vitis quinquefolia* (true), now often listed as "*muralis*," is the

large-leaved, self-clinging Virginia Creeper, which colours so delightfully before the fall. This also needs careful training and, at the proper time, severe restraint. The Common Virginia Creeper, *V. vitacea*, is almost exactly similar except that it is not provided with clinging suckers to the tendrils and, consequently, needs additional support if grown against a wall. It colours quite as well as *V. quinquefolia*. Its need for something to cling to may be utilised by providing wires to encourage its growth just where a line of shadow would be advantageous, and it will then more than repay any necessary training and tying.

It is exceedingly useful, too, for summer-houses and garden pavilions where trails of growth may be allowed to drape the entrance.

There are, of course, other useful climbers which have little or no attraction in flower or in fruit, but there are so many kinds which, otherwise ornamental, are beautiful either when in flower or, later, when the fruits ripen that, except for certain bleak corners, the kinds which do not possess these attractions might well be neglected. Of flowering climbers or, to speak more accurately, of flowering shrubs for walls, the principal genera are *Wistaria*, *Clematis*, *Jasminum*, *Ceanothus*, *Lonicera* and, of course, *Rosa*.

All the *Wistarias* are beautiful climbers, but the kinds common at present in gardens are *WW. sinensis* and *multijuga*, the latter being the one with the very long and elegant trails which certainly have freer scope on a pergola than upon a wall. Like the very long-tasselled forms of *Laburnum alpinum*, these long chains are liable to be damaged, and twisted up, too, in rough weather. From which it will be gathered that our old friend *W. sinensis* can still make out a considerable claim to attention. There are good white varieties of both species and a rosy one of *W. multijuga*, but what we will call the typical forms of both are the most attractive, though, except as regards colouring, both species vary much from seed, which accounts for the poor forms and the shy bloomers often seen in gardens. A good form is worth taking care of and propagating.

The genus *Clematis* embraces a number of somewhat diverse but all very beautiful climbing plants. For house walls the large-flowered hybrids belonging to the *lanuginosa*, *Jackmanni*, *patens* and *florida* sections are the most useful. *Clematis montana*, which is apt to be overwhelming in such a position, is excellent for covering unsightly buildings and, of course, for growing on trees. The same remark applies to the beautiful natural forms of this plant known, respectively, as *grandiflora* and *rubens*. Of the forms of *Clematis* *Jackmanni* it is doubtful if any really surpass the original plant

THE BEAUTIFUL EVERGREEN CLEMATIS ARMANDI.

THE ROSY CLEMATIS MONTANA RUBENS ON A BLANK WALL.

A GROUP OF CEANOTHUS THYRSIFLORUS EFFECTIVELY PLANTED TO FURNISH A WALL.

sent out by the famous Woking house; *C. Jackmanni* *supra* is larger, however. The beautiful Snow White Jackmanni is also in considerable request. Other excellent sorts belonging to the same section, but perhaps less well known are Comtesse de Bouchaud, satiny rose; Mme. Edouard André, velvety red; Mrs. Cholmondeley, pale mauve; and Star of India, reddish purple.

There are so great a number of beautiful sorts of the lanuginosa section that it is difficult to make a selection. The following, however, are all excellent: Beauty of Worcester, bluish violet, white stamens, produces single and double blooms on the same plant; Mabel Moser, mauve violet, barred with red; Nellie Moser, mauve, also with a red bar; Queen Alexandra, soft lavender; and W. T. Gladstone, large, fine lilac.

Of the earlier-flowering florida type Belle of Woking, double silvery grey; Comtesse of Lovelace, bluish lilac; and the double white and fragrant Duchess of Edinburgh are most noteworthy; while of those which flower in May and early June Lady Lonsborough, silver grey, barred paler; Lasur-stein, blue purple; Miss Bateman, white with chocolate anthers; Mrs. George Jackman, white and cream; and Stella, mauve and reddish purple, are among the best. For a wall with a west or south-west aspect the evergreen Clematis Armandi is fine, but there are two types of the plant in commerce, one much better than the other.

The genus *Jasminum* from the standpoint of a lover of hardy climbers seems always to promise more than it performs; indeed, there seems to be a good opportunity here for the hybridist. The white and fragrant *Jasminum officinale* and the winter-flowering, golden *J. nudicaule* are too well known to need description. *Jasminum revolutum*, though of shrubby habit, may be trained against a wall—indeed, needs to be in most districts, for it is not very hardy, and the allied *J. floridum* is a useful climber for favoured localities. The two last mentioned are yellow flowered. The rosy *Jasminum Beesianum* needs heavy pruning to produce satisfactory blossom, and even then it just muses being a valuable addition.

The *Ceanothus* family is an extensive one, but many of the species are hardy only against a wall in all but very favoured districts and, to do them justice, almost without exception they make excellent wall plants. Even the garden varieties of hybrid origin typified by the well known Gloire de Versailles may be trained on a wall, but they are less suitable for the purpose than such kinds as *thyrsiflorus* and its variety *griseus*, the related (probably hybrid) *Lobbianus*, *Veitchianus*, *velutinus* var. *levigatus*, *floribundus* and *rigidus*. Each of these produces a distinct effect, the beauty of *velutinus* var. *levigatus* consisting largely in the tough glossy foliage against which in late autumn the privet-like inflorescences shew to advantage.

The Honeysuckles attract largely by their fragrance, and, despite the very distinct colourings given in the books of reference, there is a general sameness about the whole family, at least as far as the climbing species of *Lonicera* are concerned, which we envisage under the English name. All of them are liable to attacks by aphids, especially against a south wall, and this should be borne in mind when planting. *Lonicera Periclymenum* is our well known hedgerow species, and the so-called Dutch Honeysuckle is var. *belgica*; it is easily distinguished by the more purple colouring of leaf and flower. *L. P. serotina* (or *sempervirens*) is an excellent late flowerer. The Pertoliolate Woodbine, *L. Caprifolium*, differs from our native plant in that the upper leaves on the shoots are united around the stem to form a cup. *Lonicera italyca* is a hybrid (perhaps a natural one) between *L. Caprifolium* and *etrusca*, and is, on the whole, the most desirable of them all; the variety *atrosanguinea* has reddish purple flowers. Very distinct in the terms of the Japanese Honeysuckle, *L. japonica*. The best known is probably *aureo-reticulata*, of which the veins and mid ribs of the leaves are bright yellow.

Of the multitude of excellent climbing Roses, Teas, Hybrid Teas and Noisettes, it is impossible here to write; they are worthy of an article to themselves. Besides, nothing is so uncertain as the growth of climbing varieties of ordinary bush Roses.

TOADFLAXES AND SNAPDRAGONS

THE Toadflaxes (*Linaria*) belong to the Natural Order Scrophulariaceæ, the genus comprising about 150 species, mostly found in the North Temperate regions. Consisting of both perennials and annuals, there are few plants possessed of a more elegant and attractive appearance than the various species mentioned below. For the rock garden or border many kinds are exceedingly useful and ornamental, while others may be used for the decoration of old walls. The Toadflax seems peculiarly suitable for the last-named kind of gardening, whether in shade or sun. The minute *L. hepaticifolia* and *L. pilosa* may be used for converting shady corners and crevices into attractive green carpets, studded thickly in summer with lilac or purple flowers. For the moraine garden there is the charming little *L. alpina*, with its rich purple and orange-coloured flowers set above the glaucous foliage, while for the border many of the taller kinds, such as the Dalmatian Toadflax (*L. dalmatica*), make handsome specimens and produce masses of flowers during summer and autumn.

All are of easy culture, succeeding well in light rich soil, the annuals being best sown where they are to flower. They should be well thinned out when the seedlings are large enough to handle. The autumn-sown ones make the best plants, and come into flower earlier, but where the seedlings are liable to suffer during the winter months, sowing is best deferred till spring. The perennials are also readily raised from seeds, which afford the best method of increase, although the plants may be divided in late autumn or spring. Some of the best kinds are:

L. ALPINA.—A charming little alpine from the European Alps, of perennial tufted habit, with numerous stems 2 ins. or 3 ins. high clothed with fleshy glaucous leaves and terminating in racemes of bicoloured rich purple- and orange-coloured flowers from June to September. Although it will flourish in well drained pockets in the rock garden, it is more at home in the moraine garden, where it quickly establishes itself by means of self-sown seeds, which germinate freely round about the old plants. In colour the flowers vary a good deal, there being white, rose and self-coloured purple forms.

L. ÆQUITRILLOBA is a little evergreen creeper from Corsica and Sardinia, with small, cordate-reniform leaves under ½ in. across, three, rarely five-lobed, and purple flowers in June.

L. ANTICARIA.—An annual, about 9 ins. high, with beautiful flowers varying in colour from violet to white in summer. This is a native of Spain.

L. BIPARTITA.—This North African annual grows 1 ft. high, is of tufted habit, has numerous stems, and bears racemes of violet-purple flowers from June to September.

L. CYMBALARIA (Kenilworth Ivy, Ivy-leaved Toadflax) is found wild in many parts of this country clothing old walls with its graceful procumbent stems, clothed during the greater part of the year with bright lilac flowers. A pretty form is var. *alba*, with white flowers, having a pale lemon-coloured lip. The green leaves are over 1 in. in diameter and deeply five-lobed.

L. DALMATICA.—A handsome, vigorous-growing perennial, from 2 ft. to 3 ft. high, erect stems, glaucous leaves and large yellow flowers in loose racemes. This is an excellent border plant when grown in good loamy soil, keeping up a display of bloom from June to September. The yellow flowers are characterised by the orange blotch on the lip. Native of South-Eastern Europe.

L. GENISTIFOLIA.—From South-Eastern Europe and Asia Minor, this is somewhat similar in habit to the above, but is of more slender habit, has narrower leaves, and bears slender racemes of light yellow flowers from June to October.

L. HEPATICIFOLIA. A pretty little plant for shady nooks in the rock garden, where it forms a dense neat carpet, with fleshy, entire leaves 1 in. across, green in colour, veined with white. The pretty lilac flowers are produced from June to September. It hails from Corsica, and should not be introduced among other small-growing plants as it is liable to be aggressive.

L. MACEDONICA is similar in height and habit to *L. dalmatica*, but has longer racemes of deeper-coloured yellow flowers and broader glaucous foliage. Flowers from June to September and comes from Macedonia.

L. ORIGANIFOLIA.—This is a neat little rock plant of decumbent habit, hairy foliage, and racemes

L. PURPUREA.—A good wall plant, but owing to its size, 2 ft. to 3 ft. high, it is more suitable for the wild garden, where it soon makes itself at home by means of self-sown seeds. It is of bushy habit, annual or biennial, with glaucous leaves and long racemes of rich maroon-purple flowers all the summer. It grows best in rocky places on the margins of shrubberies, often reaching a height of 4 ft., and is a European species.

L. REPENS (syn. *L. striata*).—A good border plant of spreading habit up to 2 ft. high with pale purple flowers having deeper-coloured lines. The variety *alba* is a most charming white-flowered form with elegant sprays of white flowers from June to October. This plant is found wild in parts of this country.

L. RETICULATA.—A charming annual from Portugal, growing about 9 ins. high, with deep purple, reticulately veined flowers, the palates of which are copper coloured or yellow, marked with deep purple lines. The racemes are short and crowded, and produced from May to August.

L. SAXATILIS is a yellow-flowered annual from

THE BEAUTIFUL PINK FORM OF LINARIA ALPINA.

of violet-coloured flowers having orange throats. It is an annual, but frequently reproduces itself in suitable positions, such as on old crumbling walls and rocky ledges with perfect drainage. It may be increased by means of cuttings in autumn, but is best raised from seed in the spring. It is a native of Spain and Portugal.

L. PALLIDA.—This is similar in habit to Kenilworth Ivy, but likes a moister position, and the leaves are only three-lobed. The purple flowers are of relatively large size, borne freely on procumbent stems from May to September. A good plant for the crevices of a paved walk, this comes from Italy.

L. PILOSA.—Somewhat like *L. hepaticifolia* in appearance, this species is larger and hairy all over. The leaves are seven-lobed and sometimes as much as 1 in. in diameter, green above and bright reddish purple beneath. From June to September the purple and yellow flowers are produced in great abundance. This species prefers a shady position in rocky crevices, and is, like the above, a native of Italy.

Spain and, like the above, useful for filling in gaps in the herbaceous border.

L. TRIORNITHOPHORA.—A desirable and charming perennial, the shape and arrangement of the flowers suggest, in miniature, the appearance of birds perched in threes upon the stems, hence the name. It grows about 1 ft. high, with broad, somewhat glaucous leaves, and purple and yellow flowers in summer. Not quite hardy, it is best treated as an annual and raised in heat in spring. It hails from Portugal.

L. TRIPHVLLA.—This species of Toadflax is easily distinguished from all others by the peculiar disposition of its leaves, which grow three together on the upper part of the stem. In colour the flowers vary from purple to yellow, sometimes combining both, and often one or the other. It is a native of South Europe, and is a hardy annual which may be sown outside in March or April.

L. VULGARIS.—This is our native Toadflax, common on railway and other banks. Its bright yellow and orange flowers are very attractive; Var. *Peloria* is a curious form with five spurs,

the forming a regular flower. This form is also persistent and reproduces itself true from seeds.

SNAPDRAGONS.

Very closely related to the *Linarias* are the Snapdragons (*Antirrhinum*). The genus *Antirrhinum* is not a large one, but it contains one or two species of great value for the garden. Few plants vary more than the Common Snapdragon (*A. majus*), which is frequently found growing wild on old walls in this country, and for beautiful colouring few flowers can match the popular race of garden plants derived from this species. Their period of flowering may be extended over the whole season, from early summer to late autumn, by means of sowings at intervals, and they are greatly appreciated in masses, either in the border or in beds by themselves. When the many beautiful forms are grown together they hybridise freely, with the result that flowers with a wide

It has procumbent stems thickly set with small, alternate, soft leaves grey with the silky hairs that cover both surfaces. The whole plant is sticky to the touch, as its specific name implies. It is rather tender, but easily propagated by means of cuttings and also raised from seeds, which it produces freely. It is quite at home as a pot plant in a cold frame, and is useful for the alpine house, growing about 6 ins. high and making quite a bushy plant covered with its white flowers from early May onwards.

A. ORONTIUM.—This annual is a British plant growing about 1 ft. high with rosy purple flowers. It is commonly called Calf's-snout, from a fancied resemblance between the seed-pod and the head of an animal.

A. SEMPERVIRENS.—In habit this is somewhat like *A. glutinosum*, but is rather more erect and is not so sticky to the touch, while the white flowers have a pink veining on the upper section. It is

THE PRETTY ROSE FORM OF THE KENILWORTH IVY, *LINARIA CYMBALARIA*.

range of colouring are produced. By selection, however, a number of varieties have been obtained which come true to a great extent. They may also be obtained in three distinct groups according to height, tall, medium and dwarf, ranging in the taller from 2 ft. or more to the dwarf ones, only 6 ins. or so in height. Other species worth growing are:

A. ASARINA.—This is a very pretty species, and particularly suited for a sunny ledge in the rock garden. It is of procumbent habit, with pubescent foliage and flowers generally produced in pairs in the axils of the leaves. The flowers are large and yellow, with an orange mouth, and are produced during the summer and autumn months. It cannot be considered hardy, and is often killed in winter, but as it sets seed freely and is easily propagated by means of cuttings, it is well worth a little trouble. It is a native of Italy, and has been in cultivation some two hundred years.

A. GLUTINOSUM. This is a Spanish plant which is said to grow freely in the great walls of the Alhambra at Granada, and is at its best as a wall plant. In dry walls this little Snapdragon finds a congenial home and bears its white flowers profusely through the summer and autumn.

also more hardy, being found higher up in the Pyrenees than *A. glutinosum*. Given a position on a sunny, well drained ledge or in an old wall, it forms a bushy plant, flowering profusely during the whole of the summer months. The two species cross readily, and intermediates are found in gardens combining the characters of both parents. *A. glutinosum* has also been crossed with *A. majus*, producing a plant of the habit of the latter but with paler-coloured flowers. W. I.

CAMPANULA ALLIONII

A GREAT many years ago, when I first became acquainted with *Campanula Allionii*, I treated it with the utmost awe and respect. Many picturesque things had been written about it. It was a rare, rare, high, high alpine, frightfully difficult to obtain, and when obtained most difficult to grow. To flower it would seem almost to entail a V.M.H. for the successful cultivator. So much was I in awe of Allionii that I largely left its cultivation to my very clever foreman of those days. After watching his methods of

propagation for some time, however, I came to the conclusion that he was on the wrong lines with this particular species. He was striking cuttings of it, and I do not know which detested the process most, the heads he chopped off or the roots that remained in the ground. But the heads available for cuttings were all too few in number, and when they had grudgingly rooted they were poor apologies for plants. So I grew on our best stock plant in a big pot for some time, and then one day, when the foreman had gone home to dinner, I took my big pot specimen plant, shook and washed out all the soil from its roots and pulled the white twitch-like roots into a couple of dozen separate pieces and replanted each singly in a smaller pot in a sandy, gritty scree-soil. My foreman thought this all very drastic and crude, and was sure that I had killed a valuable stock plant. Not a bit of it. Every piece grew, and from that time on our respect for the imagined whims of *Campanula Allionii* has shrunk to vanishing point, and our success in its cultivation has grown with every year's increasing confidence.

In those days I grew the magnificent old Backhouse variety of *Campanula Allionii* with enormous bells of deepest richest purple. This has now become extremely scarce in gardens, and between 1914 and 1918 it became altogether lost at Stevenage. Fortunately, I have recaptured from a friend a piece of this best of all forms, and this is now increasing steadily, so that a few years of patient cultivation and propagation should bring it back into the gardens of those who like the very best. I have collected *Campanula Allionii* many times, and although I have been to several stations where the species was extremely abundant, I have never come across anything quite so magnificent as the old form. The nearest approach was in the Maritime Alps. In a tiny border by a chalet in a valley near Tenda was a form which the owner had collected locally, and this was almost, but not quite, up to the Backhouse variety. At Mt. Cenis, *Campanula Allionii* is quite fairly abundant, but not particularly good. The bells are mostly smallish, lilac, and rather pinched into a waist. But in the neighbourhood of the Lautaret two years ago I struck a very good patch. Here the flowers were large, many of them extraordinarily long and of excellent colour—strong violets and lilacs—and the plant was growing in the wildest profusion, great patches a couple of feet across, studding the ground with dozens of huge bells, like Canterbury Bells, huddled almost stemless on the ground. Many were close to the roadside, and one could scramble far up the scree and still see Allionii far above. Although it was still gloriously in flower, and I could select the best forms, it was yet late enough in the season to harvest great stores of seed.

Campanula Allionii is a scree plant, and enjoys running about in the loose, free, stony soil of a scree garden. But it is almost equally happy in a light loam. In stiff clayey soils it is not at home. It is almost as easy going as *Campanula pusilla* if only one does not make too much fuss of it. If one fusses it, it plays up to invalid treatment and shams sick. The "moraine" garden, i.e., a scree garden made by a plumber, is quite unnecessary for Allionii. It may grow in spite of underground irrigation, but it will grow perfectly well without. In a note in THE GARDEN a little while back M. Correvon mentioned the white form of Allionii as growing in Dr. Jenkin's garden, but Dr. Jenkin tells me he has not the plant. As far as I know, live plants of *Campanula Allionii* all have never reached this country.

Stevenage.

CLARENCE ELLIOTT.

SOME OF THE NEW ROSES OF 1922

A FAIR start was made this year in the testing of some of the 1922 new Roses, though it was not found possible to get all the British varieties, and, of the foreigners, only a very few were obtainable. Taking the Hybrid Teas first in alphabetical order:

ADMIRATION (S. McGredy and Son). The creamy pink blooms are nicely shaped, though a little flat; the buds very pretty. This should make a good exhibitor's Rose. The growth is good and bushy, though rather dwarf, reaching only about 15ins. in height.

BETTY UPRICHARD (Alex. Dickson and Sons). — The excellent blooms are of a colour a little difficult

to describe; outside the petals are coppery carmine, while inside they are a lighter carmine, quite a unique combination. The blooms are not heavy, which is an advantage. The growth is bushy and tall, some shoots measuring 3ft. in height. The foliage is good, and a strong point in favour of the Rose is the mass of beautiful blooms it gives in autumn. Gold medal, National Rose Society.

CAPTAIN KILBY STUART (Alex. Dickson and Sons). This hardly comes up to expectation, perhaps, after the high standard set by Betty Uprichard. The blooms are large, deep crimson in colour and, while lacking in form, they make up for it in excellent scent. The growth is rather

dwarf, but perhaps the single plant tested was none too strong originally.

CLARA CURTIS (Alex. Dickson and Sons). The blooms are deep golden yellow and a little flat, but shapely in the bud, the growth excellent just right for a bedding Rose—about 24ins. high. It is a protuse bloomer, continuing through the autumn. The foliage is tough and dark, combining well with the yellow blooms. Gold medal, N.R.S.

COURTNEY PAGE (S. McGredy and Son). The scarlet crimson blooms are similar to those of H. V. Machin, though inclined to discolour on maturity. It is very sweet scented. The growth is good, about 18ins. high, and the foliage also

QUALITY.

THE GLOWING SCARLET CRISP
LADY INCHQUIN.

can and good. Probably it will do best in a wet season, as our plants did not seem to like drought. Gold medal, N.R.S.

DIADYM (S. McGredy and Son).—Another variety difficult to describe as regards colour, this is catalogued as a deep crimson suffused salmon and coppery yellow, but our first blooms came salmon pink and not unlike those of Los Angeles. The blooms are very large and good enough for exhibition, though a trifle flat. It is a splendid autumn bloomer. The growth is good, reaching about 2ft. in height, and the foliage also good.

FRANCESCA (J. H. Pemberton).—The small apricot yellow, semi-double flowers bloom in clusters. The buds are very pretty. It is a strong grower, making bushes 4ft. in height with good, clean foliage.

INNOCENCE (Chaplin Brothers).—This has large, single, pure white blooms with curious reddish stamens. It was very effective when exhibited at the previous summer shows arranged in vases or baskets. The growth is strong and upright, about 30ins. high, and the variety blossoms well in autumn. Certificate of merit, N.R.S.

JOHN HART (Elisha Hicks).—The bright cherry pink blooms are carried on erect stems. All the blooms come a good shape and of reasonable size, though they are not big enough for an exhibitor's box. It is a buttonhole Rose and a free bloomer through autumn as well. Described as an improved Lady Battersea, it should make an excellent bedding Rose—about 2ft. high. The foliage is good, the leaves large, and the new growths are of reddish colouring.

KATHLEEN (J. H. Pemberton).—A cluster Rose with very small pinkish bluish flowers in big trusses. The buds come red, making a pretty effect in combination with the pink blooms. It is free-flowering and the growth bushy—about 2ft. high.

LADY INCHQUIN (Alex. Dickson and Sons).—The very bright and startling orange cerise colour attracts universal attention. The growth is erect, about 24ins. high, and the foliage is small-leaved and light in colour. This is an excellent bedding Rose, a free bloomer and a wonderful sight in autumn. Gold medal, N.R.S.

LADY VENABLE VERNON (Jersey Nurseries). The blooms are creamy saffron colour with pink centres. It is a clean grower, though dwarf height only about 12ins. Origin, Mrs. A. Hammond & Sir A. N. Rockford.

LADY VEREA (Elisha Hicks). The small pink blooms have a yellow base. It is a buttonhole Rose which makes strong growth 24ins. in

height and the foliage is large and good. It produces good trusses of blooms and plenty of autumn flowers.

LORD CHARLEMONT (S. McGredy and Son).—The dazzling crimson flowers are very rich in colour and not heavy. It is a good dwarf bedding Rose height 15ins. to 18ins., and produces an excellent crop of blooms in autumn. It is said to be one of the best Roses for potting.

THE SINGLE WHITE INNOCENCE FLOWERS FREELY IN AUTUMN.

LUCILE BARKER (Elisha Hicks).—Apricot yellow blooms and good pointed buds surmount the clean and erect, though thin growth—about 30ins. high. It makes good trusses of bloom and is very free-flowering; a good bedding variety.

MABLE MORSE (S. McGredy and Son).—The bright golden yellow blooms are very full and very clean. Every flower comes a perfect shape, and it is a really free-flowering variety. Although we had regarded Golden Emblem as perfection so far as yellow Roses are concerned, this new Rose is even better, and should prove the crowning point, unless, of course, the raisers have something even better coming along. The growth is about 18ins. high, and the shoots are thrown with a branching habit. The foliage is good, the leaves being a dark bronze red. In autumn the plants are again a mass of blooms—all as perfect in shape as ever. Gold medal, N.R.S.

MRS. ALFRED WEST (Frank Cant and Co.).—This has bright pink blooms which are large and pointed. Unfortunately, our plant was not a strong one, but the growth seems to be somewhat dwarf.

PRIMA (B. R. Cant and Sons).—Creamy yellow blooms with long pointed buds and sweet scent

combine to make quite a useful and promising bedding Rose. The growth is upright but not tall—about 15ins. to 18ins.—the foliage good (leaves large), the new shoots and foliage being almost purple coloured. It is recommended for pot culture. Gold medal, N.R.S.

PRINCESS NAKAGO (J. H. Pemberton).—This is a Rose with a curious blend of colour—fire shaded yellow—which has small, semi-double rosette-like blossoms. Of bushy growth, it is about 18ins. high.

THE ADJUTANT (J. H. Pemberton).—The semi-single dark vermilion-coloured blooms are quite startling in colour. Of good tall growth, running up to nearly 3ft., the foliage is large and leathery. It threw some good autumn blooms.

WATTHAM CRIMSON (Chaplin Brothers).—The dark crimson blooms are rather like those of Elizabeth Cullen. The growth is dwarf—about 12ins. high. Too many of these very similar varieties are being put on the market.

Three varieties of Pernetiana Roses have been tried here, viz.:

MRS. BECKWITH (J. Pernet-Ducher).—The pale yellow blooms are medium full, the growth none too strong, and the height about 18ins. Of this type also there are too many similar ones being marketed, and only the best should be selected.

PRESIDENT CHERIOUX (J. Pernet-Ducher).—Quite a striking novelty. The colour is coral with the base of petals shaded yellow, and it is very fragrant. The growth is good, the habit branching, and the shoots about 15ins. to 18ins. long. This should make a wonderful show when massed in a bed. Gold medal of Honour, Bagatelle.

SOVEREIGN (B. R. Cant and Sons).—The golden yellow buds and blooms are of good shape and it is a good strong grower. The height is about 2ft., the foliage excellent, the leaves being large. It throws splendid trusses of bloom in autumn and is altogether a fine bedding Rose.

One new Tea Rose was marketed in 1923, emphasising the unfortunate decline of this once-popular race:

MURIEL WILSON (George Prince).—This has very pale lemon-shaded blooms, almost white. The growth is good, and here it does considerably better as a dwarf than on a standard. The foliage is excellent and disease-proof, and it threw some fine blooms in autumn. This will no doubt be most popular with lovers of the good old Tea Roses.

One dwarf Polyantha, viz.:

LAXTON'S PINK DELIGHT (Laxton Brothers).—Although described as a "Dwarf Poly," it has grown to a height of over 2ft. here in its first season. The blooms are single pink, and it is very free-flowering in large and erect trusses. This is a fine-weathering Rose, the colour becoming dirty in wet. It should, preferably, be classed as a single-flowering bush Rose.

It is difficult to flower climbing Roses the first season if they are properly pruned, so at present we are more concerned with habits and growth than blooming:

CLIMBING MRS. AARON WARD (Alex. Dickson and Son).—This is a climbing Hybrid Tea of excellent promise. The growth is good and strong—about 5ft. long shoots in the first year—and the foliage large and clean.

CLIMBING STEVENS (J. Pernet-Ducher).—A climbing sport of Mrs. Herbert Stevens, this in its first year has made wonderful growth—shoots 7ft. and 8ft. high, and plenty of them, too. It should be a very valuable addition to outdoor climbing Hybrid Tea varieties, provided, of course, it blooms as freely as it grows. The foliage is excellent, large and tough.

SNOWFLAKE (Frank Cant and Co.).—This is a very strong-growing Wichuriana—if anything a little too strong, though that is hardly a fault.

The large trusses of pure white blooms are carried on long shoots. It is late flowering, and should make a splendid weeping standard. We have here the best addition to the *Wichurianas* for many a day. Gold medal, N.R.S.

The above list of 1922 Roses is, of course, by no means complete, for, besides other British raisers, there is also a big list of Continental new varieties. Several of those described above stand up immensely superior to others, and they

will, without a doubt, become popular Roses of the future. Exhibition Roses seem to be on the wane—the great, heavy blooms never did seem to take the popular fancy, and with all Rose growers surely it is bedding Roses, and real good ones, that are desired.

The best yellow of the year is undoubtedly Mable Morse. The future of this should be assured, and when known to the public it will be found in every garden. Sovereign comes

second. Of reds Lord Charlemont has so far proved the best, while John Hart is runner-up. Betty Uprichard and Lady Inchiquin must be grown in every garden and massed in beds. There is little to choose between them as regards novelty and brightness. Diadem is the best pink of the year, while Phoebe, President Cherieux and Lucile Barker are all promising, and a more definite opinion on their merits can be given after another year's trial.

H. L. WETTER.

FOG AND FLOWERS AT VINCENT SQUARE

THE Royal Horticultural Society is very fortunate in the exhibitors who make its fortnightly meetings so attractive. On November 27 last the weather was so discouraging and unsuitable for transporting plants and flowers that it would not have been surprising to have found practically an empty hall. But sufficient exhibitors braved the fog and frost with their plants and flowers to make a very bright show at Westminster, though Mrs. Constance Joy had the disappointment of finding the beautiful plants of *Begonia Gloire de Lorraine* which she sent from her gardens at Maryland, Bentley, badly nipped by the frost. Although the flowers were hanging in a sad fashion, however, and the leaves had lost all their green colour, it was fully evident that before being frozen they were admirable plants.

Better fortune attended Mr. J. B. Body, who exhibited from Hindhead Court, Hindhead, a large group of magnificent *Begonia Gloire de Lorraine* in perfect condition. These were all plants in very large pots, and displayed the highest

degree of cultural skill. A silver-gilt medal was awarded, but had it been the higher award of a gold medal, no one, taking into consideration the excellence of the plants, their unusual size and the difficulties of transporting so many large *Begonias* from Hindhead, could have criticised the award.

Although Mrs. Constance Joy was unfortunate with the *Begonias*, her three specimen plants of *Chrysanthemum Mrs. R. Luxford* were in perfect condition. These model plants were of the type now but rarely seen in this country, though they are still popular on the Continent. There was little to choose between them and, curiously enough, two bore 150 flowers each, while the third had 146 blooms, and they made a bright and attractive display.

In a corner of the hall Mr. L. R. Russell set up a dozen or so beautiful plants of the orange-coloured *Jacobinia chrysostephana*, a warm greenhouse plant which is rather neglected these days. He also shewed the beautiful blue *Tillandsia Lindeniana*.

An uncommonly artistic display was made with Cacti and allied plants by Mr. Sidney Smith. Such succulents as those on view are really more valuable than is generally realised, for they do not require much heat during the winter, when the plants are at rest and should be kept quite dry. They also are very good plants for the living-room.

Another very uncommon exhibit was that of "Everlastings" set up by the French Intensive Gardens, Limited, who had grown large quantities of *Acroclineums*, *Statice*, *Helichrysums*, *Physalis*, *Tamarix*, *Gypsophila* and *Agrostis* for drying. In this they had been very successful, so that an attractive display was the result. Their idea of writing the names in white paint on the green leaves of the common Cherry Laurel was uncommon and effective. The beautiful Hare's-Tail Grass, *Lagurus ovatus* was especially appreciated by visitors.

Carnations were, of course, to be seen in bright colours and goodly quantity, and Messrs. Allwood Brothers are still able to show their dainty and

ONE PLANT OF A FINE GROUP OF *BEGONIA GLOIRE DE LORRAINE*.

THE BEAUTIFUL (ANNUAL) HARE'S-TAIL GRASS, *LAGURUS OVATUS*.

lowering *Diathus Allwoodii*. Among their combinations proper the large vase of Edward Allwood was especially brilliant. Not only is the vivid colour so valuable but the flowers of this variety keep fresh unusually long in a cut state. Jazz, Tarzan, Circe, Chintz and a vase of mixed sorts were also admirable.

Bright colour was noticeable, too, among the Carnations of Mr. C. Engelmann, who shewed Tarzan, Laddie, Topsy, Peerless, Delice and Enchantress Supreme with many other sorts. Eileen Low, their new pink variety, was prominently shewn by Messrs. Stuart Low and Co., and from the quantity to be seen it would appear to be a good winter-flowering Carnation. Two fancy varieties, Coquette and Amos Grove, were also very attractive.

On either side of the entrance there were splendid groups of *Chrysanthemums* arranged by Messrs. W. Wells and Co. and Messrs. Keith Luxford and Co. Both exhibitors had a number of excellent exhibition Japanese varieties, and also shewed many Singles and the market-sized Japanese sorts which are valuable for ordinary decorations. Messrs. Luxford and Co. had some most delightful vases of tiny Pompons of charming colouring which would help to make an uncommon decoration for a dinner-table.

Spray-flowered *Chrysanthemums* were shewn, with other cut flowers and plants, by Mr. F. G. Wood and Messrs. Baker, Limited. The latter included *Veronica salicornoides* and *V. cupressoides*, while Mr. Wood shewed his miniature rock gardens. Mr. G. Reuthe set up many sprays of interesting and useful conifers, and in some cases these bore their cones. Near his *Bromeliads* Mr. Russell had an attractive group of ornamental shrubs, which included a standard *Rosemary* in full bloom.

The Countess Cawdor sent an attractive selection of *Pernettya mucronata* which were heavily fruited. Among the several distinct forms there was one with almost transparent crimson berries which will be of great value.

The only group of Orchids in the body of the hall was a beautiful one by Messrs. Sander and Son. They displayed splendid plants of *Cymbidiums*, *Brasso-Cattleyas*, *Cattleyas* and *Cypripediums*.

The superb qualities of the rich pink *Rose America* was again fully evident in the excellent vases shewn by Mr. Elisha J. Hicks. A collection of well trained topiary was arranged by Mr. J. Klinkert.

Messrs. G. Bunyard and Co. had a small collection of beautifully coloured Apples in such sorts as Cox's Orange Pippin, Rival, Peasgood's Nonsuch, Allington Pippin and Baumann's Red Reinette.

During the winter the exhibition of paintings and garden sundries is encouraged, and on the present occasion Miss Winifred Walker, Mrs. Townsend, Miss Ellen Warrington, Miss A. F. Wilkinson, Mrs. Adie and Miss Maude Angell took advantage of the opportunity to shew paintings of beautiful and interesting gardens and studies of flowers; while Miss G. Dorrien-Smith had interesting paintings of such subtropical plants as *Mesembryanthemums* and *Metrosideros*, which thrive in the mildest parts of the country.

NEW AND RARE PLANTS.

Cypripedium Chrysostom Amy Moore.—This is a splendid example of the large *Chrysostom* type of *Cypripedium* *insigne*. The flower is immensely enlarged and of perfect form. The broad upstanding standard is pure white on its upper half, spotted with crimson-chocolate, while the lower portion is a metallic green with chocolate markings. The lip and sepals are of *C. insigne*

colouring, but more shining, and the broad leaves are a dark pea green. First-class certificate. Shewn by Mr. G. F. Moore.

C. Chrysostom Richard Fort.—This is another immense bloom of the same type as the foregoing. The erect standard is well marked with rosy spots on white ground on the upper portion and chocolate on green below. First-class certificate. Shewn by Mr. G. F. Moore.

C. Gwen Hannen.—Although not quite so large as the two previous varieties, the flower is very large and of similar type. There is much more white on the standard and a line of crimson-

chocolate spots runs up the middle of the standard. First-class certificate. Shewn by Mr. G. F. Moore.

C. Prince Albert var. Mecca.—The colouring in this variety is delightful and uncommon in its type of *Cypripedium*. The standard is faintly tinged with blush and heavily spotted with crimson-chocolate. The sepals are definitely marked with shining chocolate colour along the upper half, and are shining green with chocolate spots below. The lip is the same as in *C. insigne*. It is a more rounded flower than the foregoing. First-class certificate. Shewn by Mr. G. F. Moore.

THE ALONSOAS

Wanted—a Developer.

NATURE is full of undeveloped plates. Ought human beings to try to develop them? Different temperaments will doubtless answer the question in different ways. Again, human agency differs from "Rytol" (a famous developer) in that it has more power of influencing the negative. What is the kind of influence that we would wish to see? The answer is as before. Different temperaments have different ideals. This is the point where the fat gets into the fire. There is as it were but one garden, but there are diversities of opinion as to what should go into it. Because it is so must all of us rest content with the happy-go-lucky development of Nature, which, in other words, is being content with the wilding treasures which are sent or brought from other lands? Their most ardent lover surely has a vulnerable heel which at some time or another has been pierced by the spear of some man-made beauty. Nature as often as not invites us to begin the work. Among the gardeners who appreciated to the full natural forms may be numbered the late garden-genius, Reginald Farrer. Have I not heard him talking about his well beloved *Eritrichium nanum* when on one occasion he staged a large exhibit of it at one of the great Shrewsbury shows? All were beautiful but the flowers were not all alike. This blue was better than that; this flower had wider petals than the other; and there was no comparison about habit of these two. Farrer was not satisfied with taking quietly all that Nature gave him.

I feel sure Nature did not blame him for picking and choosing—nay, by her presenting him with a choice, she invited him to do so. I am not an alpine man, but I believe this tiny plant is very tricky and difficult in English gardens, so perhaps no development has been attempted. But this is far from the case with everything we are given. Last summer "that ever was" I collected together all the species and varieties of *Alonsoas* that I could lay my hands on. The chief impression that remains with me now the venture is over is that the *Alonsoas* are a neglected family. There are potentialities lying dormant which only need a Mr. Human Rytol to come along and take them in hand. Nature herself "gives the tip" in the little differences that may be seen in the build and colouring of the species and varieties which we now have. Encouragement is at hand not only in the inborn curiosity of mankind to see the pig that is in the poke, but in the more tangible reward that arises from the desire of the novelty-loving public to possess themselves of the "latest out." Mr. Human Rytol has, nowadays, an easier task than he would have had a quarter of a century back, for he has Mendel's "hypo" to help him in his work

and to shorten his labour. Even this is being altered, and William Bateson's Improved Mendelian Hypo is, in this connexion, a gift from the gods.

Last summer I saw with my own eyes something of what I may call the innate variability of the race, and I believe it was no fool's paradise that I filled with my imaginings, but a veritable *paradisus terrestris* made beautiful by new and fascinating flowers. Not that all developments are on right lines. I could not bring myself to care for the wretched-looking dwarf *Mutisii* any more than I like Cupid Sweet Peas. *Mutisii* in what I believe to be its primitive state, has pale and washy pink flowers, and there seems to be no gain in associating the colour with dwarfness. But other changes in other directions are possible. Visitors to my garden this year saw a beautiful mass of bright salmon rose *Alonsoas*. It all came from a solitary plant in a large bed of *Mutisii* which had brighter and deeper-coloured flowers than the others. Then Warszewiczii has told me that it is not wedded to one particular shade of red for the colour of its coat. I have had some getting on to the yellowy red of the *Tulip Marksmann*, while others have been of a deeper dye and have recalled the dark blood red of *William Pitt*. A slight difference, too, was observable in the shape of the blooms. Some surfaces were all in one plane and in some there was the usual depression of the centre.

When one sees the straight branches of *Myrtifolia* it is only natural to suppose that those of *acutifolia* might be straightened by rigid selection. The great big reddy orange flowers seem to ask us to do at least this favour for them; but if only we could give them the grand leafage of *myrtifolia* (*Vilmorin*)! You know the garden Stinging Nettle. Imagine its really beautiful leaves made of a fresher and a more glossy green, and then you will know what it is that *acutifolia* is longing for. The flowers of *myrtifolia* are much smaller, rather paler in colouring, and more sparsely placed on the shorter spike. They see those finer ones of their brother's and in turn beg us to do something for them. *Linearis* or *linifolia* is characterised by the narrowness of its leaves. It has orange flowers with a small dark depressed centre—as in *myrtifolia*—and extra long spikes of bloom. Surely something might be made out of this last-named characteristic. If I were a younger man how I should like to have a go at them. From what others have done in dwarfing *Mutisii*, from my own experience in deepening its colour, and from the variations which I have observed in Warszewiczii, it would appear some Mr. Human Rytol ought to set to work to develop the possibilities of this charming family. All floral development work is both exciting and fascinating. There is an old local saying of which

the first meaning is very plain, but which with a changed application puts my case in a nutshell. "He's too far gone with the brandy bottle to turn back to the buttermilk ladle." I have tried to be a developer of Nature, and I can only say that the continual pleasure which I derive from the attempt is such that it would be sorry to have to turn back to the buttermilk ladle of more or less aimless gardening, which appears to be "the end-all and be-all" of many. I know, too, of a certain young man who had to bear as his lot in life anything but robust health, who in the occupation of trying to raise new or better forms of garden plants found a something which quite counterbalanced his being unable to take part in games or ride or shoot as others of his own age and standing were wont to do. Bacon, if we may gauge his mind by his posthumous "*Sylva Sylvarum*," if he had had a modern gardener's knowledge of the potentialities which lie hidden under the outward faces of many natural forms of flowers, would have had an additional reason

for describing gardening as "the purest of human pleasures and the greatest refreshment to the Spirits of man." Alonsoas are among those which are waiting to be taken in hand. If so much has been done with the *Clarkia* and the *Schizanthus*, why should Alonsoas lag behind?

Cultural hints are outside the purpose of this article, but in case anyone feels he would like to grow them it may be pointed out that seed should be sown, if possible under glass, in February, so that there may be good strong plants ready for potting in their permanent quarters in May. They require a long season in the open if we are to get any seed. If, however, bad weather comes before this is ripe, the plants should be lifted and put into the greenhouse to complete the process. I have never tried increasing them by cuttings, but dictionaries tell us it may be done, for most of the species in their own homes are perennials. I have used the names I have found in seed lists, but I very much doubt if they are correct.

JOSEPH JACOB.

CORRESPONDENCE

THE OLYMPIC MULLEIN.

I HAVE already said so much in *THE GARDEN* about the Olympic Mullein that I must apologise for saying yet another word or two about its persistent flowering. My plants began flowering in the last week of June. They were still, on November 8, quite four months later, putting forth blossom. On the last two days of September, two of the finest days of the year, the plants were covered thick with bloom, almost as much so as when they were at their best. This long period of bloom is, I fancy due partly to the exceptional wetness of the season and partly to the absence of frosts. A vaseful of *Verbascum* sprays gathered a few days ago is now in full beauty, fresh bloom coming out day by day. I notice also for the first time that the flower has a fragrance—slight, but sweet.—SOMERS.

Last autumn I went with a botanist on some interesting trips from my little mountain cottage. We have, growing among the mountain debris, several

THE CHINKERICHEES.

I ENCLOSE a photograph of two kinds of *Ornithogalum*. The cut specimens were received from South Africa on October 22, having been sent over in cold storage during the three weeks' voyage. The flowers were exhibited at the Royal Horticultural Society's fortnightly meeting on November 13, and this photograph was taken on November 21, at which date they were still in excellent condition.—(Miss) IDA E. WRIGHT, *Kew, Surrey*.

NEW ZEALAND RANUNCULI.

I HAVE had so many interesting and delightful correspondents in answer to my little articles on New Zealand alpine, that I feel tempted to try to describe a few more.

TWO VARIETIES OF CHINKERICHEES, *ORNITHOGALUM LACTEUM* AND VAR. *CONICUM*.

Ranunculi. One, *R. Haastii*, has a leathery, brown-grey, much cut leaf—I say leaf because each plant has only two leaves at the most, generally only one—and one blossom is thrown up about the size of half-a-crown. *R. Enysi*, with smaller leaves, is a smaller plant altogether.

R. paucifolius has a whole article to itself, by Professor Wall, in the transactions of the New Zealand Institute. It grows in a basin in the limestone district of Castle Hill. This is the only place where it has ever been found. The leaves are leathery, it dies down completely in the winter and has a blossom 2 ins. across. The New Zealand Institute says: "Originating in a very remote drought period, somewhere within an extensive

area of Tertiary limestone, this plant acquired xerophytic characters and flourished. Then followed the glacial period, which gradually covered all the area except this small basin which escaped."

There are now about 300 plants left of this, one of the oldest living kinds in the world. Then, of course, there is the wonderful *R. Lyallii*, white, with the huge round green leaves, so handy for drinking cups, but my favourite is the old, old *R. paucifolius*. I hope to collect seeds of several kinds this season, especially of *RR. Haastii*, *Enysi* and *paucifolius*. Would anyone like to try them? If so, I will gladly send some.—MARY POULTON, *Shirley, Christchurch, New Zealand*.

THE COLIN PULLINGER MOUSE TRAP.

IN February of last year I addressed a letter to you with regard to my experience of the usefulness of the "Colin Pullinger Balance Mouse Trap" for the capture in a garden of field mice and voles, and have been much surprised to receive letters from different parts of the country stating that the traps had not caught a single mouse.

Knowing how well the traps work it did not occur to me until recently to enquire of my gardener how my own had been catching and I was astonished to learn that they had not caught any mice for a long time, although a drop of oil of aniseed had been placed on the flannel of the bait rack every few weeks.

As oil of aniseed has been the only bait used for my traps for the last forty years and only now has failed to attract, it occurs to me that during the war some alteration was made in its manufacture, but it will be very difficult to prove this, for on enquiry I have learnt that most of this oil is distilled in China. I am also informed that there are several common brands on the market from which a portion of the active constituent (Anethol) has been removed, so this may be the cause of the failure of the oil to attract. Several specimens have been sent to me, but according to my sense of smell they are neither as pleasant nor as strong as the oil of years ago.

I am informed that Messrs. Duke, Waring, Crisp and Co., who are now the sole manufacturers of the trap, on seeing my letter, attached a slip recommending oil of aniseed as a bait, and this probably has led to it being used more widely than it would otherwise have been done.

However, knowing the fondness of mice for cheese, I had the scented flannel removed and replaced with a slice of cheese about 3 in. in thickness (the size of the bait rack) and since this was done the traps have caught as well as they used to do.

I feel it a duty to let you know what has occurred, for many of those who purchased traps on seeing my letter have probably been disappointed with the result, if they have followed the advice given to bait only with oil of aniseed.—MARK HOVELL.

THE YEAR'S FRUIT CROP.

THE season has been a remarkable one for most kinds of fruit, and especially so as regards the contrast between gardens and orchards in close proximity. The show of Apple blossom was all that could be wished, and generally, in spite of a cold May, the fruit set well: but then came disaster. In this district we had a bitterly cold drought from the middle of May to almost the end of June, with the result that the Apples neither grew nor thinned themselves, and this was followed by a terrible plague of green fly; I only remember one year when fly was equally bad and then the conditions were the same. The fly seems always with us and only waiting favourable conditions to multiply by myriads, and as soon as there is a check to growth the fly appears. This year, the attack was so bad that where the

trees were not pruned, nearly all the foliage was destroyed, necessitating new growth, which speaks badly for next year's crop. I found a mixture of paraffin and soft-soap was amply sufficient to destroy the pest, and on the Apples one application enough if done thoroughly, but the difficulty with large trees was too great for my appliances, so I concentrated on smaller trees bearing valuable crops. Unhappily, this was not all. The fruit hung in bunches, the one chance of decent Apples being persistently to thin, and only the thinned trees produced fruit of any quality. Some of the larger trees, such as Dunelow's Seedling and Branley's Seedling, were smothered with crowds of little Apples only fit for pigs. While in some orchards there was an immense crop of Apples, good and bad, in other orchards close by there were few or none. I came across two large orchards of young healthy trees without an Apple. I cannot explain these vagaries. I have heard several explanations, but careful investigation shews that none of them will solve the riddle. Nature has her secrets which we cannot yet fully fathom.

Pears were almost a blank and, I think, not for climatic reasons, but because the enormous crops of last year were too great a strain for a crop this year. One of the banes in fruit growing is over-cropping, with the result of poor fruit and little or none the ensuing year. Of the wall fruit, Apricots and Nectarines did well, but Peaches were scarce. Plums were, generally speaking, a failure. I had plenty of Victorias and Orleans, probably owing to vigorous thinning last year and spraying for fly this summer. Strawberries were badly affected by the drought and cold June, and in some places the crop was nil. It is rarely the case but that we have a dry spell in June or late in May, and I find that the only way to get a crop in a rather light soil is to drench with water during this spell. If sufficient water is given to get as deep as the roots and the plants are then strawed, one or two applications are sufficient. Raspberries and Gooseberries were, on the whole, a good crop, but Currants suffered severely from the drought and cold.

On the whole, the year has been a disappointing one, and probably those whose Apple and Plum trees bore no fruit will be better off next year than those who had large crops of inferior and, in many cases, useless fruit this year. Looking over the Apples I have been surprised to find very few diseased ones. The maggoty ones seem to have fallen before the crop was gathered, and I noticed at that time how few were attacked. Some of my neighbours complain of Apples failing to keep an annual complaint—but I am sure in most cases it is the result of bad gathering and storing. My gardener handles Apples as he would eggs, and he does so with excellent results. It must be understood that I am not writing of the fruit crop generally, but only in my own district (the East Midlands), but I believe my remarks apply to the Cambs. and Isle of Ely orchards, with, no doubt, many exceptions.—J. H.

NERINE BOWDENI.

[NOTED with interest the article by "X." on *Nerine Bowdeni* outdoors at Kew in THE GARDEN for November 24, page 612. We have here an old-established bed of *Nerine Bowdeni* situated at the base of an 8ft. Yew hedge facing full south from which this year we have cut over eight dozen spikes of flower. The bed (area about 6 square yards) was one blaze of colour and a sight not to be forgotten. It is remarkable that *Nerine Bowdeni* is not more generally grown in gardens considering its beauty in the garden and its usefulness as a cut flower for indoor decoration. This, with the *Belladonna Lily* and *Crimm Powellii*, the two latter of which have

flowered most profusely here this year at the foot of south walls, gave a choice supply of cut flower from early August till the end of October.—HERBERT J. BECKINGHAM, *Exhurst Park Gardens*.

ILEX VERTICILLATA.

THOUGH usually included with the evergreen species in the genus *Ilex*, this interesting deciduous shrub retains Linnaeus's name of *Prinos verticillata* in a few gardens. A native of

CRIMSON BERRIES OF ILEX VERTICILLATA, A NEW-WORLD DECIDUOUS HOLLY.

Eastern North America, the Winterberry was first introduced in 1736. That such a beautiful and distinct berried shrub is comparatively little grown is not easy to understand. My theory for its want of popularity is that the deciduous Hollies are frequently unisexual. Hence, to be successful, they should be planted in colonies, as is done with the evergreen Hollies, to ensure pollination; whereas, what usually happens, is that an isolated bush or two is planted and, failing to fruit, the plant is not persevered with.

At Kew the large bed devoted to the culture of the deciduous Hollies contains five species and several varieties. These are *I. Amelanchier*, *decidua*, *levigata*, *serrata* (syn. *Sieboldi*) and *verticillata*. A sixth species, *I. geniculata*, is in the arboretum nursery.

They thrive best in a moist loamy soil, a mulching of manure in summer being beneficial. Seeds and layering are the favoured methods of propagation.

I. verticillata is a shrub of spreading habit, 6ft. to 8ft. high, a beautiful sight just now with myriads of scarlet berries glowing in the autumn sunlight. Next in point of value is *I. serrata* (syn. *Sieboldi*) from Japan, where it is said to form a large bush, or small tree, up to 15ft. or 20ft. in height.—A. O.

STRAWBERRIES AND CLEMATISES.

WHEN I read the culture of Strawberries by Mr. Copley (page 412), I thought, "What a sensible article," and made up my mind then and there to adopt his plan in future, even after reading Mr. Engleheart's methods of culture on page 409, which, I think, is rather an expensive way for those who have only a small garden, setting quite aside the risk of a doubtful stock. In an editorial to a

further note (page 506) you say "it is not easy to follow our correspondent, Mr. Copley," but had you obtained some maiden plants and half of them turned out practically worthless, as mine have done, with a kind of malformed fruit about the size of a Hazel nut and not worth picking, and which had to be dug up and burnt, then you would realise that this sort of thing would be less likely to happen if the runners were obtained from one year old plants that had fruited, as Mr. Copley suggests.

I would also draw your attention to Mr. C. Comfort's remarks in "Gardening of the Week," page 472, where he writes, . . . "not merely to set fruit. . . ."

There was another subject I was greatly interested in and that was the controversy some while ago on the Clematis. Notwithstanding what nurserymen say, I think your Gravetye correspondent's method of culture is sound, and I should like to try Clematises on their own roots, if he would inform me where I might obtain them; I have purchased from our local nurserymen three Jackmanni and all have failed.—W. GATER, *Sheffield*.

[Mr. Robinson's method at Gravetye with newly-bought-in stock of Clematises is to wash away all the soil from roots and then, with a sharp knife, to sever the already rooted scion from the stock. If any readers know where layered plants may be procured, perhaps they will share the information with our correspondent.—ED.]

THE SLUG NUISANCE.

HAVING read with much interest the articles on "Slugs Rampant," by "T. A. F.," on page 557, and "A Slug Trap," by "E. F. S. W.," on page 583, it might be of interest to many of your readers to know that a spoonful of golden syrup or treacle in a tin half filled with water makes a good slug trap. Plunge the tin up to the rim where slugs are troublesome. It is surprising how they find it out after a day or two. The trap may be left for a week and then the slugs which have drowned themselves may be thrown out and the tin refilled. Syrup tins are most suitable. I get them unwashed from the kitchen, half fill them with water and they are ready for use.—P. T.

ALPINES FROM THE PASS OF MONT CENIS

LEAVING London on the very hot evening of July 14 last I arrived at Modane, on the borders of Italy, the next evening, and up on to the top of the Mont Cenis pass by the midday following, being whirled up by motor. There are magnificent views of the mountains on either side of the Valley of the Arc, which was traversed by Termignon and Lanslebourg, the pass diverging away from the Arc at the latter place. Passing glimpses were had of dwarf Campanulas, Dianthi and many others *en route* which would have pleased one to have made a closer examination of. I was, however, one only of a number of passengers, most of whom were too intent on arriving at their destination to brook delay for the examination of plants, no matter how rare or beautiful.

However, when well on to the higher part of the pass something went wrong with the car, and advantage was taken of this for a little exercise. A look round about revealed a few plants of interest, including *Silene acaulis* in flower, but past its best at this level—probably a little over 5,000ft. up. In a very short while we were away again, and from this point it was rather a heavy grind, but about midday we arrived at the top of the pass and the Hotel de la Poste, which was the terminus and my destination. The view from the top of the pass (6,893ft.) is magnificent, with the lovely Lac du Mout Cenis below in the foreground, and, beyond, the encircling mountains, including the Little Mont Cenis and the higher snow-capped mountain peaks, also a fine lake. A splendid setting and probably containing one of the richest floras in the whole of the European Alps lies within a not very large radius of the hotel. Other "alpine" enthusiasts were in residence (all boarded out in the "dependence" above the cows and other inhabitants of the lower part of the premises) and others of note had just left. There is no wonder at the locality being an attractive one when you have within a stone's throw of the hotel, on the quartz outcrop, a bewildering number of good plants either on the tops or in the deep limestone-like potholes such as occur in the limestone region of North-West Yorkshire and which here are clothed with plants from top to bottom, many probably existing in the shelter provided by these that would not survive if exposed to the occasionally rough weather conditions on the pass.

It must be rough up here at times to warrant twenty-three refuge huts being provided in a comparatively short distance on the upper portion of the pass. The plants on this ground and also around the lake are noticeable for their luxurious growth and brightness of colour, many of them very different from similar species seen in other localities, reminding one more than anything of the luxuriousness of the plants in the New Forest at home as compared with the same in less favourable districts. Sauntering round the rocky outcrop on the hotel side of the lake revealed, among many other interesting species, *Alissum alpestris*, shrubby and somewhat leggy; but, higher up, this was much smaller and quite compact, as was also *Biscutella laevigata*.

That is the way with many alpenes: they would be desirable if they would maintain their dwarfness and compactness at the lower levels, instead of, as too often when tried in our gardens, developing into larger and looser and much less desirable plants. *Calamintha alpina grandiflora* with its lovely masses of violet blue flowers, was noticeably abundant, even on the banks along the roadside, together with a very fine form of the shrubby *Thymus Chamadrys*, and one of the best

dwarf creeping Veronicas, *Veronica Allionii* with its shrubby foliage clinging to the ground and delicately beautiful blue upstanding flower-spikes. A striking contrast to this was the Alpine Sainfoin, which was quite a feature in places, with its drifts of brilliant red flowers, and well worth reproducing in our gardens, that is, if sufficient space could be spared to make it an effective feature. *Potentilla aurea* with its orange-spotted bright yellow petals and the large yellow-flowered *Helianthemum grandiflorum* were well distributed, but the shrubby and smaller-flowered *Helianthemum alpestre* occurred more rarely. The *Bupleurum ranunculoides* was quite a good flowered form. *Asperula cynanchica*, the somewhat uncommon English Squinancy Wort, has very much finer and larger flower-spikes than is usual and is known as *Asperula cynanchica* var. *Jordanii*. The Alpine Skullcap, *Scutellaria alpina*, here has strikingly large violet-blue flower-spikes that would be a desirable

the purplish blue *Campanulas rhomboidalis* and *linifolia* with the fine stately blue-flowered *Phyteuma spicatum* and the rarer dark purple-flowered *Phyteuma Halleri* were quite a feature on the southern side of the lake. In the wetter parts *Polygonum bistorta* was the outstanding flower with its coral-coloured short flower-spikes, large masses of which were very effective. In the adjacent pastures was the smaller white Viviparous Knotweed, *Polygonum viviparum*, a plant that occurs quite freely in some parts of North-West Yorkshire that I am familiar with, and of which I have plants in the garden of some years' standing. *Allium roseum* was fairly plentiful at the west end of the lake, many of the flowers just having their heads above the water-level.

Leaving the vicinity of the lake and following a stream valley a little distance back from and parallel to the road leading from the top of the pass towards the Italian Donane, on the

SILENE ALPESTRIS IN THE ALPS.

addition to any garden and very different from so many of the plants one sees under this name. *Cerinth minor* was one of the more interesting plants in the "potholes" with its not very striking greenish flowers, also a Lungwort, *Pulmonaria angustifolia*, and *Senecio Doronicum*, one of the finest of the larger alpine *Senecios*. It was much too late for the "masses" of *Gentians* which are in bloom hereabouts earlier on, and, due to the hotter season than usual, many flowers were over that are usually at their best at this period.

While *Anemone alpina* was plentiful in the district, it was altogether out of flower, but I could not understand there being practically no visible sign of its striking fluffy seed-heads. They could hardly have "flown" at this early date, and it was scarcely likely that they could have been collected. The only reason I could see was that, possibly, frosts at the time of developing might have prevented them from setting. The rich meadows that were uncut had quite a good sprinkling of the always beautiful *Salvia pratensis*, which is of rare occurrence in the wild state in England. Drifts of

lovely green grassy banks *Viola calcarata* was at its best, very fine and interestingly variable, blue, beautiful yellows and almost white flowers occurring, but usually in dainty simple colours (except for the dark markings at the base of the petals)—one of the daintiest and sweetest of this lovely group. But I am not inclined to admit that our mountain forms of *Viola lutea* in the North of England are not equally beautiful and interesting, especially so as seen in the upper pastures and rich meadows in June, and which not only have considerable colour variation, but also, in addition to the simple colours, have a more extensive range, in that you find flowers with the two upper petals a deep velvety purple with the lower petals yellow, or the two upper petals a deep purple blotch encircled with yellow (a very striking and beautiful variety), or, again, with the upper portion of the two upper petals purple and lower portion yellow. Yet another has just a purple fringe (or picotee edge) to the yellow upper petals. All the above have the lower petals yellow. You also have an interesting range among the blue flowers, including the variety *amena*, and forms

with upper petals deep velvety purple with lower petals paler, purplish flushed, sometimes with yellow shading from eye upwards. All these forms I have at present, raised from seedlings taken from the wild plants. Pardon this digression, which I hope the Editor will pass and readers excuse; but it had to come out: I have a very fond liking for our native, which I am inclined to think does not get the praise it merits. Continuing along the stream more *Viola calcarata* together with quite a number of *Gentiana verna* were seen in flower, but not in the sheets that you have in these parts earlier in the summer and only lingering here along with *Primula farinosa*, a usual associate owing to the valley lying towards the north and being to a considerable extent sheltered from the sun. Further along, *Ranunculus aconitifolius* was in abundance. Coming up from the valley towards the pass a very fine stretch of outcropping schist was beautifully relieved by masses of *Dianthus neglectus*, *Sempervivum arachnoideum*

and Alpine Sainfoin, all in varying shades of red and providing an effect, if it could be reproduced, that would be a revelation, say, among the embankment rock gardens at the Chelsea Show. Crossing the road leading down to Lanslebourg, the Alpine Toadflax was fairly plentiful, including a noticeable variety with petals of a delicate, almost lavender blue without the usual orange markings, which gave it quite a distinctive appearance. Since returning I find that this form is already recorded from this district and is known as the var. *concolor*. *Campanula pusilla* was abundantly in evidence. It is extremely pretty and very much at home in most of our rock gardens. One of my greatest difficulties is to keep it from over-running rarer, if not choicer, plants. Some belated *Soldanella alpina* was seen and the extremely pretty *Saxifraga androsacea*, like an *Androsace* (one of the best) as its name implies.

Middlebrough. T. ASHTON LOFTHOUSE.

(To be continued).

THE MECHANICAL TREATMENT OF SOILS

THERE is a very great deal in the skilful management of soil; more, in fact, than in the judicious application of manures, animal or chemical, and, while it is sheer folly to be niggardly or neglectful in the matter of replenishing nourishment, it is a certain fact that much manure is put into land that fails in the purpose for which it is applied, not by reason of any shortcoming in the manure, but because the mechanical condition of the soil has not been carefully studied and taken into account.

To a great many people the one idea is that, apart from manure, what the soil, any soil, requires is lime, and only quite recently I read in a newly published book that the gardener should never be afraid of using lime.

There are, it may be readily granted, few things so valuable to the gardener as lime, but it is going too far to make so sweeping a statement as that the gardener need never be afraid of using lime. Many soils contain sufficient lime, and to give more is waste, to say the least of it; worse than that, there are many soils that are not in a condition to stand lime, and it may be distinctly injurious to such soils. As a matter of fact, lime, although so constantly talked about, written about and so largely used, is very imperfectly understood by quite a large proportion of horticulturists. It is highly essential that we should study carefully the nature or mechanical condition of the soil before applying lime, and we must also keep clearly in mind that there are several forms of lime, and their action varies so much that upon the character of the soil depends the particular form of lime that may safely be used.

SANDY SOILS.

Let us consider a very sandy soil, loose, porous and excessively dry. It consists mainly of finely pulverised particles of stone and, as every gardener knows, it is most essential that humus shall be added, without which plant life cannot thrive. Even if sandy soil contains less lime than should be found in a soil of well balanced analysis, it would be very unwise straightway to apply a dressing of ground lime, caustic or fresh slaked lime, because as soon as the lime is buried in the soil it will seek something to attack, and since it cannot burn the sand, which is nothing but particles of stone, it will burn up what little humus is present and thus leave the soil poorer than ever.

The only safe form of lime to use on a sandy soil is chalk in powder form, and before even that is used it is advisable to test the soil for lime. The simple test is to place a little soil in a

convenient vessel, such as a jam jar, with about three times its bulk of water, stir it up until the soil is thoroughly mixed with the water, and then pour in a little hydrochloric acid. If there is considerable effervescence, there is plenty of lime in the soil, the effervescence being less vigorous in proportion to the deficiency of lime. There are various methods of mechanically improving sandy soil, first among which, of course, is the incorporation of marly clay, but this must be properly done. It is useless merely to dig in rough lumps of clay. It should be evenly spread over the surface before Christmas and left until a fine dry spell in February, when the frosts and air will have pulverised it so that it may be raked down to form an even mulch. In that condition it may be dug in, but stop digging if rain comes on to make the clay pasty. A vast amount of benefit may be afforded a sandy soil by sowing some cheap annual Lupin seed and, when the plants are just shewing flower-heads, digging them in. It is possible to raise and dig in two crops in a season, and the benefit is most remarkable. It is after such treatment as this that both animal and chemical manures may be used with advantage, whereas, previously, they would do but little good because the same rain that dissolved them would wash away all their nutrient salts.

CLAY SOIL.

Next in point of difficulty, so far as improvement is concerned, is the stiff, tenacious clay that cuts like soap when moist and bakes like bricks when dry. Yet, with all its faults, clay may be made better garden soil than sand or gravel.

Where the subsoil only is clay, covered with light soil, the first thing to do is bastard trench, but where the clay comes to the surface and has not previously been well cultivated, it is quite unwise to attempt to tackle the subsoil until the top spit has been dealt with. Ridge digging is the first step, throwing the soil into ridges roughly in clods with intent to leave as extensive a surface exposed as possible. Stiff clay is bound to be deficient in lime, otherwise it would be less adhesive. It will, therefore, be well to sprinkle among the clods as ridging proceeds a pound of ground lime to every square yard.

It possible, dig a good-sized hole and excavate a quantity of subsoil clay from a corner of the garden and thoroughly burn it on a smother fire. After pulverising the burnt clay spread it evenly over the ridges. It will help immensely to open up the soil. Either leave the hole created open to form a drainage pit or fill it to within 18 ins. of the top with brick rubble and stones to form

a soak-away. Early in spring apply river sand or sea sand if available, or as a last resort finely sifted coal ashes, spreading evenly over the surface, and then digging and levelling. After this treatment the whole plot will benefit by bastard trenching, and another pound of lime per square yard may be worked in as digging proceeds, but not if stable manure is dug in at this time.

One must not expect to make a stubborn clay a freely working soil in one winter, but the work the following winter will be far less arduous,

SICK AND SOUR SOILS.

There are more manure-sick soils than is generally supposed, and also in town gardens soils that are sour and acid through the constant burying of green garden refuse and house garbage, and sometimes from saturation with soapsuds, which are so often reputed to be "good for the garden." Here again lime becomes essential, and two dressings during the winter will do a power of good. The object of making two dressings is not for the purpose of increasing the quantity so much as to prolong the period of activity of the lime. If a soil is very sour and, as we may term it, "stale," it will not hasten its recovery to put a very liberal quantity of lime into it, because the pace at which chemical conversion of organic nitrogen in buried vegetable matter can proceed is slower than the pace at which the caustic properties of the lime will exhaust themselves. On the other hand, a mere sprinkling of lime will start the process of sweetening, and if followed up by further light applications at intervals of a few weeks, the work will proceed unabated and the utmost benefit will be derived from the lime. If sour land can be forked over three or four times during the winter, much benefit will accrue, but with the proviso that it shall not be dug when in a saturated condition nor when hard frozen.

Probably the most baffling proposition the town gardener may have to face is the question of drainage of a water-logged soil. Even in large establishments it is no trifling matter to have to deal with stagnant water, but with careful planning it is generally possible in gardens of wide scope to devise a drainage system even if it involves digging pits, cutting ditches and laying field drain pipes. Such plans and schemes are frequently impossible in gardens hemmed in by other people's property, but something has to be done because a water-logged soil cannot make a satisfactory garden. Obviously, it is utterly futile to bury drainpipes if no outlet can be provided for the water that enters them, and one may not simply discharge surplus water into neighbouring property. To describe a perfect system of drainage is simply vexatious to those who cannot possibly carry it out. It becomes a question of compromise.

In a London garden I occupied for a number of years the ground lay in a hollow with the water frequently standing a foot from the surface. I opened a good-sized pit at the end, near the drain that took the rainwater from the house roof, and into this pit I ran a single drain pipe diagonally across the garden, and simply baled the water from the pit into the rainwater drain which, of course, ran into the sewer. Had I laid side drains as well, the influx would have overwhelmed the capacity of my pit, so, instead, I made a soak-away in the farther corner of the garden by filling a hole with brickbats and stones. Around the soak-away I planted strong-growing *Polygonums* and one or two other rank-growing shrubs that absorb a great deal of moisture, and this dual scheme, rough and ready though it was, and certainly economical, very well answered its purpose and enabled me to grow practically anything I wanted. The point to note is that without some such scheme no amount of manuring would have made that spot a fertile garden. A. J. MACSELF.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Potatoes.—A few early Potatoes are always appreciated, and where the necessary heated pits exist a start may soon be made. The tubers should be set up in trays or shallow boxes and stood in a warm house or pit fairly close to the roof glass. When the tubers are nicely sprouted some tin. pots should be well provided with drainage, over which is laid a portion of rough turfy loam. The tubers should be placed midway between the top and bottom of the receptacle and the shoots just covered with soil. Ordinary loamy soil will suffice, and later on as growth develops more compost may be added. Encourage a short, sturdy growth by keeping the plants well up to the glass, and do not subject them to a higher temperature than 50° to 55°. Afford water in moderation, but do not let the soil become dry.

Rhubarb is often in great demand, and it is a crop that pays for good cultivation. Few plants respond more freely to deeply dug ground and plenty of manure. If the roots have not been transplanted for several years, half the bed should be lifted, the roots divided and replanted 4ft. apart. Strong single crowns are the best, and the top of the crown should be about 2ins. below the surface. Make the soil fairly firm around the roots and then lightly prick over the soil between the plants, afterwards keeping the ground free from weeds. During the first season the plants should be allowed to get well established and not a single stalk be removed. Beginners often err in this direction and wonder why they never secure those long, luscious stalks which the plant can produce.

The Flower Garden.

Planting Trees and Shrubs.—When making a selection of these a thought should be given to the berry-bearing section, and in these days the Berberises, both species and hybrids, play an important part. Since the introduction of *B. Wilsonæ*, others have been imported, and some very fine hybrids have been raised. I have found that the *Wilsonæ* section bear their fruits most profusely if planted where the soil is not too rich. They are very effective when planted in suitable positions in the rock garden. Other noteworthy berry-bearing plants are the various *Cotoneasters*, especially *CC. frigida* and *bullata*; *Pyracanthas coccinea*, *Lalandei* and *angustifolia*. The *Ericas* constitute a beautiful group of plants, either for beds or in front of taller shrubs. Where the soil is free from lime they will succeed, but most positions chosen for *Ericas* may be improved by adding sandy peat and leaf-mould. Here, *E. carnea* is associated with *Rhododendron Early Gem*, and in some seasons when the weather is congenial the effect in February is very charming. Other useful Heaths are *Veitchii*, *cinerea*, *mediterranea*, *codonoides* and *arborea*. Some of the *Lilies* would succeed in the *Erica* beds, but there are a few exceptions, such as *L. Henryi*, which will only thrive in a loamy soil. Another group of plants to remember comprises those that produce beautiful autumn tints. It includes the Japanese Maples, *Parrotia persica* and *Liquidambar styraciflua*. Of flowering trees and shrubs also there is a wealth from which to choose, and, when planting, make the holes large enough to take the roots without any cramping. The soil should be trod firm and, where necessary, a stake should be employed to keep the plant in position until it becomes established.

The Hardy Fruit Garden.

Propagation.—The small or bush fruits may be increased by cuttings, and in two or three years they make quite nice bushy specimens. Gooseberries, Red and White Currants may be taken in hand during the next few weeks. Healthy shoots should be selected and made into lengths of 1ft. or 1½ins., removing the basal buds, with the idea of forming plants on a single stem. They may be set in lines 18ins. apart and a distance of 1ft. allowed between the cuttings. Choose an open site and keep the ground free from weeds during the coming season, no other attention being required. Black Currants may be treated likewise, but it is not necessary to remove the basal buds. See that each cutting rests on a firm bottom and is not suspended, which occasionally happens with the beginner if a setting pin is used.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),

Castleford, Cheltenham, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Onions.—Owing to the cool, sunless summer, many Onions were imperfectly ripened, and are therefore not keeping well. Go over the stock frequently and remove all decaying bulbs, as, if left, they will infect those around them. Retain the well ripened bulbs for late use.

Parsley.—Those who made a sowing in a frame for winter use will now be reaping the benefit of their forethought. Failing this, or the placing of a frame over the outdoor crop, a few light Yew or Fir branches thrown over a portion of the crop when hard frost threatens will prove of considerable benefit.

Foot Scrapers.—Every well appointed garden is provided with a footscraper at the junctions of the walks, for, failing this, the walks cannot be kept clean, more especially on heavy soils. The following is an efficient and inexpensive type of footscraper: Materials required for each, two redwood standards 24ins. long by 2½ins. square and a piece of light, narrow bar iron 15ins. long. Make an incision 1½ins. deep with a saw on one end of each standard and point the other end. Smear the entire standards with tar. When the tar has dried fit the bar of iron into the incisions in the standards, leaving a clear space of 12ins. between them. Stand them in the position they are to occupy and make a slight impression on the soil with the points of the standards. Pierce the ground a little with a stout iron rod to make it easier to drive the standards. Place the scraper in position again, then with a heavy wooden mallet drive the standards 15ins. into the soil and the work is complete, except that the standards may be painted green or some inconspicuous shade.

The Hardy Fruit Garden.

Gooseberries.—Bushes often get thrown out of perpendicular by the action of storms. If taken in hand soon after the mischief has been done, they can generally be restored to their original position by slackening the soil a little with a fork on the windward side, then, having carefully pushed the bush back into place, the ground on the leeward side should be trodden firm. Where this work has been neglected for a year or more it will be impossible to restore the bush to its original position without injuring the roots. In this case endeavour partially to get it back into place, and to keep it there support it by means of a stout forked piece of branch, the one end inserted a little way into the ground, the stem of the bush being caught in the fork at the junction of the lowest branch with the stem.

The Fruit-Room.—Keep the room closed during windy weather, also during rain, fog or frost. If frost is severe it may be necessary to protect the fruit with some light material, such as clean wheat straw or a double sheet of tiffany. Remove the protecting material, however, as soon as the frost gives way. Ventilate the room freely on calm, dry days. Keep a close eye on the fruit and remove any decaying specimens. Should any variety show signs of shrivelling, it should be used as soon as convenient, although it may be a late-keeping sort.

The Flower Garden.

Plants in Frames.—These include such kinds as *Pentstemons*, *Chrysanthemums*, *Pansies* and *Violas*, and *Lobelia cardinalis*. Damp is the chief enemy to contend with during the winter months, so the frames should be kept closed during frosty and wet weather. During mild, dry weather the lights should be entirely removed during the day to keep the plants as sturdy and hardy as possible.

Covering Unsightly Objects.—There are sometimes undesirable objects about a garden which cannot well be removed. It is desirable, therefore, that they should be hidden, more especially during summer, when one wants to take full advantage of the garden. The following rapid-growing climbers are all more or less suitable for this purpose: Among *Roses* can be recommended *American Pillar*, *Blush Rambler*, *Carmine Pillar*, *Electra*, *Félicité et Perpétue* and *Mme. Alfred Carrière*. Other suitable plants are *Clematis montana*, *C. m. rubens*, *C. Vitalba*, *C. Viticella*, *Forsythia suspensa*, *Jasminum nudiflorum*, *J. officinale*, *Polygonum baldschuanicum* and *Lonicera Periclymenum* (Common Honeysuckle).

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Hydrangea paniculata grandiflora.—This fine plant is very useful for conservatory decoration. Assuming that the plants have just been obtained, they should be placed in 7in. or 8in. pots. After potting, they should be stood outdoors, plunging the pots to their rims in ashes or surrounding them with hay to protect the pots from frost. When they are taken indoors during the spring, they should be pruned hard back, as the flowers are produced at the end of the current year's wood. They do not require a high temperature, 50° to 55° being quite high enough, and when in full growth they enjoy ample supplies of water at the root.

Hydrangea Hortensia Varieties.—Where it is desired to have an early batch in flower a number of plants that show prominent flower-buds should be selected and placed in a warm greenhouse, watering them carefully until growth becomes active, when they enjoy ample supplies of water at the root. The main batch of plants in cold frames should be kept as cool as possible, taking care, however, that they are not exposed to severe frost, as this might injure the dormant flower-buds.

Frames.—Plants in frames should be carefully watered during the dull days. Any necessary watering should be done during the morning, as this will allow excessive moisture to dry up somewhat before night. So far as possible, bright mornings should be selected for this purpose; while, on bright days also, the cleaning and rearranging of the plants should be carried out. Where the frames are heated, special attention as regards watering should be given to the plants standing near the hot-water pipes. Protecting material in some form should be used even if the frames are heated, as protection conserves the warmth during the night and does away with the necessity of hard firing during cold spells. According to the class of plants in the frames ample ventilation should be given, regulating this, of course, in accordance with the outside weather conditions.

Hippeastrums.—Where it is desired to have plants in flower early in the New Year bulbs should now be selected. For this purpose select from plants that were started early last season. It is also an advantage if they are in good condition at the root and do not require repotting. After soaking them thoroughly at the root some of the surface soil should be removed and replaced with a top-dressing of rich compost, at the same time examining the bulbs for mealy bug, which, if unchecked, will soon ruin a collection. It is a great advantage, especially for early work, if the pots are plunged to the rim in a bed with bottom-heat at command. Water should be sparingly given at the root until the flower-scapes are well advanced and growth commences.

Fabiana imbricata.—This pretty and interesting plant, which looks as though it should be a Heath, is a native of Chili, and is hardy, especially on walls, in the South and West. It is an ideal plant for the unheated greenhouse or conservatory, either planted out or grown in pots. This plant is easily increased by means of cuttings of half-ripened shoots during the spring, inserting the cuttings in pots containing sandy soil and standing them under a bell-glass in a cool greenhouse or cold frame. It grows freely in any good potting compost.

Erica australis, *E. codonoides* and the hybrid *E. Veitchii* are hardy in the South and West, but in the colder parts of the country require the shelter of a cool greenhouse during the winter months. They are all ideal plants for the unheated greenhouse and it is surprising that they are not more generally grown for this purpose. Their successful cultivation presents no difficulty; in fact, if so desired, young plants may be planted out in a bed of light loam and peat during the summer months, lifted during the autumn and placed in suitable-sized pots. By this means much better plants can be obtained than if they are grown throughout in pots. They are easily propagated by means of cuttings during the spring or autumn, using small twiggy shoots for this purpose. Insert the cuttings in pots containing sandy peat and stand them under a bell-glass in a cold frame, or they may be dibbled in patches in a prepared bed in the open and covered with bell-glasses. In the colder parts of the country *E. carnea* and *E. mediterranea* might also with advantage, be used for the decoration of the unheated greenhouse.

Royal Botanic Gardens, Kew.

J. COUTTS.

The Variegated Wax Flower.—The variegated Wax Flower, *Hoya carnosa variegata*, is very handsome and attractive. The green of the type plant is streaked and splashed with creamy white, so that, as the plant is an evergreen, its decorative value is high in winter as well as in summer and when flowering. It is capable of attaining a length of 10 ft. and does well either planted out or in pots, while a winter temperature of 50° to 60° is ample to ensure its comfort. The soil should be used in lumps—the roots do not take kindly to it when made too fine. Water freely all through the summer, but reduce the supply as autumn draws on, until, from November to February, only very moderate supplies indeed should be given. Each spring, a portion of the surface soil should be scraped away and replaced with fresh loam to which a little peat has been added. Many growers of both the green and variegated *Hoya*, get into trouble because they grow it in too high a temperature, with the inevitable result that mealy bug makes its dreaded attack and is then difficult to dislodge. The temperature advised above is a sufficient one, and where this is not exceeded, the plants keep singularly free from pests of all kinds. The variegated variety is a free-flowering one, the blossoms being of the typical waxy appearance and spilling their excess of honey upon anything that happens to be growing beneath them. Care should, however, be taken to grow the plants—whether on the roof or clothing a pillar—so that the shoots are thinly disposed and that light and air can circulate very freely between them. Light is absolutely essential, and the *Hoya* always flowers best when absolutely unshaded and close to the glass.

Euphorbia Cyparissias.—For the good border or rock garden this *Euphorbia* should be tabooed,

but there are many places where it might be introduced with profit. These are wild or semi-wild places, and, for example, on a dry sandy bank, where little else will grow, it will prove an acquisition. It grows about a foot high and has very beautiful finely formed foliage of a pretty green, which in autumn changes into a delightful variety of hues, from yellow and orange to reds of different shades. The clustered heads of flowers, which are individually small but in the mass are not ineffective, are of a greenish yellow, rather brighter than this term would suggest. They last a good while in good condition, and are not at all to be disdained in the summer months. The fault of this Cypress-like *Euphorbia* is its inveterate tendency to roam about and send its shoots up all about the neighbouring quarters. By means of its underground runners it soon occupies a considerable space, hence the suggestion that it is most suitable for a rough spot or a sandy bank, where it may be planted without injury to choice flowers. But for this failing of spreading too freely at the root *Euphorbia Cyparissias* would be much more frequently cultivated.

Answers to Correspondents

FLOWER GARDEN.

PRIMROSE FOLIAGE ATTACKED (G. L.).—The Primrose leaves appear to have been attacked by red spider during the past summer and possibly also by green flies. It would be well to see the conditions are moist enough to prevent the red spider attack in future, and, possibly, sulphur might be dusted on the foliage—if the underside can be reached—with advantage.

THE GREENHOUSE.

CHRYSANTHEMUMS UNSATISFACTORY (Hants.).—The Chrysanthemums have probably had a check since the buds began to form, possibly through low temperature or mistakes in watering.

FRUIT'S UNDER GLASS.

GRAPES UNSATISFACTORY (U. W.).—Either some scale insect or mealy bug is attacking the Vines or plants growing near them. These should be sought and destroyed during the winter, and all seen should be killed by touching them with a brush moistened with methylated spirits.

TREATMENT OF NEWLY PLANTED VINES (Hants.).—Any time during the last half of December the Vines should be pruned. The young canes should be cut off 18 ins. above soil level. Dress the cut ends with styptic or painters' knotting to prevent bleeding when the sap rises. Allow the Vines to start their new growth slowly early in March; train up a leader and two side shoots—one on each side—stop the latter when they are 3 ft. long and the leader when it is 6 ft. long, but allow another shoot to grow on from the extreme end of the stopped leader. Next winter, prune back the side shoots to two eyes or buds and the leader to 2 ft. from point of current year's growth. It would be good policy not to allow any bunches to ripen the first year.

MISCELLANEOUS.

POINSETTIA FLOWERS (S. B.).—We presume our correspondent refers to *Euphorbia pulcherrima*. The stems should be cut off through a joint early in a morning, the cut end being at once dipped in dust-dry sand or charcoal, or the cut ends may be seared with a red-hot poker. When placed in water as much as possible of the stem should be immersed. Usually, to avoid loss of sap through cutting, these flowers are used for decoration growing in the pots. The yellow *Arum* should be treated much the same as the white-flowered variety; but, as it is less robust, smaller pots are advisable and a lighter compost.

NAMES OF PLANTS.—T. H. Cumberland.—*Polypodium polystachyum*.

NEW SPRAYING MACHINES LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete without a Sprayer, in fact a Sprayer is absolutely essential to obtain best results.

During the War we supplied a considerable number of our well known Four Oaks Knapsack Sprayers—Rubber Diaphragm type—to the Government, and we have just re-purchased a small quantity back again, which have never been used. They are

made of copper but painted Service grey colour. They have various special additions to the ordinary machines, and the price to-day would be £5 each. We guarantee them to be in perfect working order as new. We will send one machine carefully packed, carriage paid, on receipt of 50/-, but cash must accompany all orders. We would supply 2 machines for 90/-, carriage paid.

Please mention this Paper when ordering.

SEEDS AND SEEDLING RAISING

Some Essentials to Success.

SOME months ago (August 18, p. 421) we discussed seed-raising fairly closely as it applied to alpine and herbaceous plants. To-day we propose to view the matter from rather a different angle. Many amateurs find that their own self-saved seed germinates better than that bought in—this especially with regard to certain families of plants. The inference is often drawn that the purchased seeds are either old or diluted with old seed, but it may safely be stated that in the case of reputable firms there is no ground for such a suspicion, the fact being that many seeds deteriorate rapidly after cleaning. Others which are equipped with a feathery pappus to facilitate distribution, such as those of Aster, Cineraria and Gerbera, may not suffer actual damage in the cleaning, yet may fail to germinate through the unnatural manner in which they are sown. Carried by the wind on their pretty "parachutes," they settle down, in a state of Nature, in some sheltered corner, the weight of the seed just sufficing partially to bury the seed in the earth. Germination is then rapid and easy. When, however, the seeds are sown broadside-on in a pan and covered entirely with compost, decay is very apt to set in. In the case of large seeds, such as those of Gerbera, it is not difficult to distinguish the blunt end, which bore the pappus, from the pointed one which should enter the soil; the seeds may then be placed one by one on end and half-buried in a compost with a very sandy surface. With smaller seeds of the same class we can but employ a very sharp compost, sow thinly and take care not to overwater until

germination has taken place. Thick sowing is especially detrimental, because if rot once starts it is then quickly communicated to the whole of the seeds in the pan.

Seeds which have a very hard cuticle represent another problem. Generally speaking, such undue hardness develops after the seeds are gathered, so that freshly gathered seeds germinate fairly quickly and quite readily, yet it is wiser on the whole, if saving one's own seed, to gather such before they are quite ripe. All Sweet Peas look much alike when ripe, but every practical grower is aware that while the lavender varieties have small wrinkled and mottled seeds so soft as to be readily subject to decay before germination can take place, many other sorts have seeds—especially when grown and ripened in California—as hard as those of Canna and approaching that of the Nelumbiums. The careful filing of a notch through the epidermis opposite to the scar,

though a tedious business where many seeds have to be sown, is the generally accepted way of solving the difficulty. Soaking in water at a temperature of 100° F. or so for twenty-four hours is also helpful but less reliable than the filing, and it is by no means certain that it does not affect the vitality of the germ.

Hard seeds, however, need not be large. The slowness of germination of the seeds of most Gentians must be due to hardness, since, given appropriate treatment, they usually give an excellent percentage of germination when, at length, they put in an appearance. Treatment with hot water of the temperature stated appears to have no effect, detrimental or otherwise, in their case, though to keep the seeds, when sown, in a warm greenhouse temperature is, oddly enough, fatal.

A phenomenon well known to chemists but, so far as we are aware, still imperfectly understood is the increased chemical activity of nascent gases.

Though no chemical change is involved, water in a similar way certainly has a greater penetrative power when newly thawed from snow than it otherwise possesses, and top-dressing pots of slow-germinating seeds with snow, so that they may be saturated with snow-broth, is a time-honoured and proved method of hastening and, in some cases, even of ensuring germination.

Seeds of hardy Primulas, though not exactly on all-fours with those of the Gentian family, inasmuch as the fertility of the seeds falls rapidly when there is delay in sowing, nevertheless may have their germination facilitated by the snow treatment. It is passing strange that while

THE BEAUTIFUL LITTLE CYTISUS ARDOINI.
All Broom seed should germinate readily.

only of the *Androsace* in the closely related *Primula*. In some instances the botanists have disagreed as to which of the two genera should be credited with certain species, yet the seeds of *Androsace*, almost without exception, keep better and germinate more quickly than those of the *Primula*.

Not is it always the rarest and most precious *Primulas* which present the most difficulty in raising from seed kept for half a year. Seeds of the easy and beautiful *Candelabra Primulas* seem to resent storing as badly as any, but if sowed before fully ripe and stored in a cool place in pods (this necessitates keeping the pods upright), they keep better than if packeted.

Seeds with very oily envelopes, such as are borne by many umbelliferous plants notably by the species of *Fernula*, are exceedingly slow to germinate. Probably germination might, in their case, be expedited by treating them with dilute hydrochloric acid just as is done, commercially, with Tomato seed. Such treatment, however, is best left until a very short while before seed-sowing, and there lies the difficulty, for the amateur does not like to "mess about" with acid and the seed-houses do not sell all their packets at the same time of year. Fortunately, comparatively few amateur growers have any desire to raise the Giant Fennels. With regard to Tomato seeds, since we are on the topic, there seems no sufficient reason for treating these, since they undoubtedly germinate better, albeit more slowly, when left untreated.

It is a fairly frequent complaint that various choice forms of Saxifrages are difficult to germinate, but this, in our experience, is not so. It is far more probable that, in such cases, the seeds have either been washed away by rough watering—they should always be watered by dipping the pan almost but not quite to soil level—or have been sown on an unsuitable compost and have germinated—they are very tiny at first—and died. The seed is so very fine that even when one has made a special effort to sow thinly they come up almost like "Mustard and Cress."

Enquiries come to hand occasionally as to the raising of *Broomus* from seed. Now, given fresh seed, there is nothing easier to germinate, and few things which more quickly grow up and get out of hand than the various species of *Cytisus* and *Genista*. In the case of bought seed, however, which it is intended to sow early in the year, it is well to soak it for twenty-four hours in water immediately before sowing, to sow in pots—pans are not deep enough—and place in a rather cool greenhouse. Germination may then be erratic, but it should be fairly certain.

The *Ranunculaceae*, for the most part, have hard seeds by no means easy to germinate, especially if kept. Their hardness, too, is a little deceptive, as they are, very generally, green in colour. The Hellebores, for instance, typified by the Christmas and Lenten Roses, are slow to germinate although germination is commonly very even when it takes place—and very slow-growing indeed. The choicest of the *Ranunculi* are equally slow and far more uncertain, and the same applies to some of the *Anemones*, but those with flutty seeds are, as a rule, quicker to germinate, but easily destroyed by rot before germination can take place. The likes and dislikes of the particular species as regards lime must always be borne in mind when preparing the compost.

If a very soft and porous compost is necessary for *Linum catharticum* and Saxifrages, it is still more essential for succulent plants, which, as far as hardiness is concerned, hints itself pretty much to *Sedum*, *Sempervivum* and *Opuntia*, with *Lewisia* and *Mertensia* rather than for favoured scabrics. Too much importance cannot be attached to the selection of a good pot.

THE HARD-SEEDED *TROLLIUS ASIATICUS*.

PRIMULA PULVERULENTA BY WATERSIDE; *PRIMULA* SEEDS QUICKLY PERISH

ANOTHER HARD-SEEDED PLANT, *HELLEBORUS CORSICUS*.

ORNAMENTAL BRAMBLES

THE species of Rubi include a number of ornamental shrubs, some of which are climbers, valuable for the embellishment of the garden. They include both evergreen and deciduous plants, varying considerably in habit of growth and leafage. The non-climbing species are adapted for planting in the shrubbery border, or as groups in the pleasure grounds, wild garden or woodland. The climbers are well suited for training over arbours and pillars.

The introduction of many new species from China has at least doubled the number of Rubi which we may consider good garden plants. From a purely ornamental standpoint a number of the Chinese introductions are of little value. The botanist, however, has a rich field of interest. During one expedition alone, that of 1907-8, Mr. E. H. Wilson collected seeds of fifty-one species and varieties.

The Rubi grow in most soils and positions, but to obtain the best results the ground should be well cultivated. The section for which most attention should be given to the soil comprises those with attractive stems in winter. To aid in the production of the vigorous young growths trench and liberally manure previous to planting.

PROPAGATION.

Seeds provide a ready means of increase, and seedlings as a rule grow vigorously. As, however, Brambles cross-pollinate readily unless the clumps are more or less isolated, there is always the possibility of the seedlings not coming true. Those which form large clumps or rootstocks can usually be increased by suckers or offsets, such as are produced so freely with cultivated Raspberries. Quite a considerable number are readily increased by root cuttings, a notable example being the white-stemmed Chinese Bramble, *R. Giraldianus*. One of the simplest methods of propagating most of the Rubi is by layering. This is a very simple matter in most cases, inasmuch as the ends of long arching shoots frequently develop roots where they touch the soil. Though rooting from cuttings is not much practised with Brambles, it is quite feasible, the best results as a rule being obtained by the use of a sand frame in full sun.

For pruning, the Rubi can be readily divided into two types. Those with biennial stems, which are in the majority, should have the older ones cut out to the base after fruiting. These include the popular white-stemmed Brambles and *R. odoratus*. With *R. deliciosus* and the evergreen species—*R. bambusarum*, *R. flagelliflorus*, etc.—it is simply a case of thinning and removing pieces of the older stems when crowded.

The annual cutting down of the stems, in time, causes the development of large woody rootstocks. These maintain the development of vigorous young stems for some years, and then, as in the case of Raspberry plantations, the young shoots weaken. It is time then to renew the stock with young plants.

A number of species form large clumps with stout stems and more or less arching branches from 6ft. to 10ft. or more in height. These are attractive for massing in the pleasure grounds and woodland, particularly those with white stems, which are especially effective with an evergreen background.

The species with long, slender, trailing shoots, more especially the evergreen type, are useful for pillars, arches and arbours, the evergreen kinds providing a permanent feature throughout the year.

The most beautiful Brambles in leaf are found among the newer Chinese species, for in addition to the evergreen species *R. bambusarum* and *R. flagelliflorus*, the white-stemmed *R. Giraldianus* and *R. thibetanus* have very attractive foliage.

Half a dozen Rubi, at least, should find a place in a representative collection of hardy flowering shrubs. These are *RR. deliciosus*, *nigrobaccus flore pleno*, *nutkanus*, *odoratus*, *thyrsoides flore pleno* and *ulmifolius var. bellidiflorus*.

As these notes are intended to draw attention to the decorative uses of the Brambles in our gardens, their best known value as fruit-producing bushes need only be mentioned in passing. The Blackberry as a cultivated plant is far from receiving its due value as an autumn fruit, especially for preserves. Because it is a common wayside

for the vigorous spiny stems, which are often 3ins. in circumference near the base and 10ft. or 12ft. high.

THE BEST FLOWERING BRAMBLE.

Pride of place at the head of this list must be given to the Double Pink Bramble, *Rubus ulmifolius var. bellidiflorus*. This is a very valuable summer-flowering shrub, producing quantities of blossoms on cylindrical panicles during July and August. Growing well in sun and partial shade, this flowering Bramble is useful for sunny banks and shrubbery borders, open spaces by the side of woodland walks, and valuable for a boundary hedge where the space is not too limited.

A useful companion plant is the double white variety *R. thyrsoides var. flore pleno*. Both

FRUITS OF THE "WHITE-WASHED" RUBUS BIFLORUS QUINQUEFLORUS.

fruit its very much improved value when cultivated in the garden is by no means recognised.

WHITE-STEMMED BRAMBLES.

R. biflorus, the Himalayan Bramble, is the best known of these "white-washed" species, but it now has at least four rivals among the Chinese introductions. One, the most vigorous of the group, has been named *var. quinqueflorus*. It has vigorous white stems 10ft. or more high and matures a very good fruit (a golden yellow Raspberry) in late summer.

R. Giraldianus, which Mr. E. H. Wilson first introduced from Szechuen in 1907, is a vigorous species with long, arching stems 10ft. to 15ft. long, but as they curve gracefully the height does not often exceed 8ft. or 9ft. This and *R. thibetanus*, which has blue-white stems, have very handsomely cut foliage. The latter, when first introduced by Mr. Wilson from Western China, was named by the late Mr. Rolfe and exhibited as *R. Veitchii*, but, unfortunately, the name of *R. thibetanus* had been previously given to dried specimens by Franchet and, being the older name, must be adopted. *R. lasiostylus*, introduced by Dr. Henry, has blue-white stems, and *R. niveus*, introduced by Mr. Wilson, is notable

are forms of British wild Brambles. If layering is not practicable, these double-flowered Rubi can be increased by cuttings. Healthy young side shoots taken off with a thin heel of old wood root quite well in a heated or cold frame from July to September, using sand or a very sandy compost. Readers who have a sun (Paris) frame can readily root the double Rubi therein.

R. deliciosus has pure white flowers in May, 2ins. across. It is a very beautiful shrub, quite distinct in habit from all other Rubi, being a spreading bush more like a Ribes than a Bramble when not in flower. In flower, it suggests a single white Rose with a Currant leaf. A native of the Rocky Mountains, *R. deliciosus* was first introduced in 1870. The origin of the name is obscure, for the flower is scentless and the fruit, at least on cultivated bushes, of no value. This is one of the few Rubi that should be planted in rich well prepared ground. Layering is the best method of propagation.

R. nigrobaccus, the High Blackberry of Eastern North America, has rim. wide white flowers freely borne on terminal inflorescences up to about 11t. long. June is the flowering season. Even better and more lasting in flower is the double-flowered variety *flore pleno*.

Another common Bramble from Eastern North America is *R. odoratus*. Though first introduced in 1860, it has not a superabundance of hardy flower-lovers. *R. odoratus* with its fragrant purple blossoms is not much grown. This and the next two Brambles are readily increased by division, as they sucker and the clumps spread freely over the surrounding ground. *R. nutkanus*, the Salmon Berry, is a strong-growing deciduous species 3 ft. to 6 ft., sometimes more in height. It has pure white flowers about 1½ ins. across in terminal clusters during June. The Salmon Berry is a Western North American species. *R. nobilis* is a hybrid between *R. odoratus* and the Raspberry, *R. idaeus*, with purplish red flowers during June and July.

THE CLIMBING BRAMBLES

are best represented among the Chinese species. *R. bambusarum* was introduced by Mr. Wilson in 1900. The slender, clinging, spiny stems and dark, usually trifoliate, green leaves are perhaps seen to the best advantage when twining round a stout wooden pillar in a shrubbery or mixed flower border. *R. flagelliflorus* is another evergreen

species from China with attractive metallic green leaves, the undersides clothed with light brown felt. A third species also introduced by Mr. Wilson is *R. Henryi*. This has a three-lobed leaf, not trifoliate as in *bambusarum*. Another elegant evergreen Chinese species for pillars is *R. Playfairi*.

Asked to name the best ten species, my choice would be: For flower, RR, *dehensis*, *odoratus*, *ulmiflorus* var. *helidiflorus* and *thyrsoides* fl. pl. For winter effect (white stems) RR, *bulbosus* and var. *quinqueflorus*, *Grahamii* and *thibetanus*. For evergreen foliage, RR, *flagelliflorus* and *Playfairi*. A. O.

THE DAY LILIES

THE Day Lilies belong to the Natural Order Liliaceae, the genus *Hemerocallis*, consisting of some ten species, members of which are found from Central Europe to Temperate Asia, China and Japan. They form a group of very hardy, easily grown and ornamental perennials, which are admirably adapted for the herbaceous border or for forming effective masses in wild garden or woodland. Many of the taller-growing species are handsome plants of tufted habit, long arching foliage and tall flower-stems carrying several large and beautiful flowers. This fine genus of hardy plants has been much improved during the last few years by the addition of several new species and hybrids, and the flowering period of the whole is spread over from May to September.

The prevailing colour of the flowers is yellow, but of many varied and beautiful shades, commonly tinged with bronze and coppery red. One drawback to the popularity of the genus is the short length of time the individual flowers last in good condition, but in the case of some species, like *H. flava*, which produce quantities of flowers daily, the brief life of the individual is less noticeable. All are moisture-loving plants, they increase freely, and many require frequent splitting up to keep them within bounds in the border. This freedom of growth renders them valuable for informal gardening where broad groups are required, and where the plants can spread at will. Some

A "CLOSE-UP" OF *HEMEROCALLIS FLAVA*.

of the smaller kinds, like *H. minor*, may even be introduced to the rock garden, where places could be found for them among taller-growing plants at the back. All are easily propagated by means of division either in autumn or spring, and seeds germinate freely when sown as soon as they are ripe. The following are some of the best species and hybrids of the genus in cultivation:

H. AURANTIACA.—A little-known plant, supposed to be a native of Japan, forming a clump over 2 ft. high and as much in diameter. The flower-stems are carried above the leaves and bear from five to eight orange flowers 6 ins. to 7 ins. long and 6 ins. across. It does fairly well in light dry soils.

H. A. VAR. MAJOR is one of the finest plants in the genus. The leaves are arranged in broad distichous tufts that are quite characteristic of this plant. It is somewhat erratic in flowering, some blossoms being produced in July, while others do not open till September. The flower-stems are about 2 ft. high, reaching just above the foliage, but not erect, and bear from five to nine flowers of a rich orange colour, the segments of which are exceptionally broad and long, forming flowers some 8 ins. in diameter. This plant likes plenty of moisture and requires to be well established before it flowers freely. If the site is dry, the plants should have heavy and frequent waterings to develop growth. Manure is not required, simply moisture and a sunny position.

H. CHINA.—This is one of the newer species from Northern Shensi in China, having been introduced into cultivation at the beginning of this century, when it was distributed by Lemoine of Nancy. It forms a handsome tuft in the way of *H. flava*, with long, arching leaves and flower-stems reaching to a height of 3 ft. to 4 ft. These bear several citron yellow flowers, the segments of which are from 4 ins. to 5 ins. long and ¾ in. wide. There are two plants in cultivation under this name, one of which is merely a form of *H. flava* with shorter and deeper yellow flower segments. It flowers in June.

H. DE MORTIERII (SYNS. *Sieboldii* and *rutilans*).—This is a plant of small habit, making graceful little tufts 1 ft. high and producing soft yellow

HEMEROCALLIS FLAVA BOLDLY GROUPED.

coloured flowers on stems over 1ft. high in umbels of four or five. They average 2½ins. in length and width, and are heavily flushed with reddish brown on the outside of the outer segments. A peculiarity of this plant is that the flowers do not always open to their full extent. The leaves are slender and grass-like, while the flower-stems are not erect but stand out at different angles from the plant. It is a neat little plant, well worth a place in the border, and flowering in June.

H. FLAVA.—The common Day Lily is a European species, and one of the best for all purposes. It produces ample leaves in dense but graceful tufts 2ft. high and as much through, and numerous flower-stems towering high above the foliage. These each bear about a dozen canary yellow flowers from ½ins. to 1ins. long and ½ins. across, with broad inner segments and narrower outside ones. Alike suitable for the border or wild garden, this species is a general favourite with its perfectly shaped and beautiful fragrant flowers, which are borne from the beginning of June to August. There is a hybrid between this species and *H. fulva* of intermediate habit.

H. FORRESTII is a new species from Yunnan, China, where it was found by Forrest in 1906 growing in dry clefts and on ledges of cliffs in side valleys of the Lichiang mountain range at an elevation of 9,000ft. to 10,000ft. It is allied to *H. fulva*, but differs in its narrower flower segments and remarkably short flower tube. It grows from 12ins. to 18ins. high, with deep reddish orange flowers in June. It was introduced into cultivation by Bees, Limited.

H. FULVA (syn. *H. disticha*).—A European species, but also found in Siberia and Japan, this is a strong-growing plant of rambling habit with broad green foliage and tall flower-stems reaching a height of 4ft. The coppery red, crimson-shaded flowers, ½ins. across, with crimped segments, are produced freely from June onward. It is one of the best for the wild garden, as it grows in almost any kind of soil, preferring a strong loam, but is at its best on the banks of a small stream where the water is within reach of the roots. There are several varieties of this species, one, called var. *Kwanso* with large double flowers of a coppery orange shade. Var. *variegata* has silver striped foliage which is very effective in contrast with the orange flowers.

H. MIDDENDORFII.—A native of Eastern Siberia and Japan, this species makes a compact and dense tuft of narrow foliage 18ins. high, and produces quantities of stems bearing deep, orange-coloured flowers flushed on the outside with reddish brown. These are like those of *H. Thunbergii* in size, but are arranged in a close umbel of five each, borne just above the foliage. It is a good garden plant of neat habit and moderate growth, free flowering and one of the earliest, coming into bloom in May. The flowers are somewhat variable in colour, especially in the amount of darker marking on the outer segments.

H. MINOR (syn. *H. graminea*).—This plant makes a neat tuft only 6ins. high, and is well adapted for a place in the rock garden, where it will thrive in a warm sunny position. The pale yellow flowers, in umbels of five, are produced in July. It is a native of Eastern Siberia, China and Japan.

H. THUNBERGII.—A fine late-flowering species from Japan, this is one of the taller kinds, reaching a height of 4ft. or more. It produces dense tufts of somewhat narrow foliage 2ft. high, above which are borne large quantities of pale sulphur-coloured flowers each 2ins. across and ½ins. long. A very free grower, it makes a great display of bloom in July and August, especially when growing near water or in good strong soil. There are several forms of this species in gardens, and it is one of the parents of *H. × luteola*.

HYBRIDS AND CROSSES.

Hybrids in the genus are numerous, of which one of the best is *H. Apricot*, with richly coloured flowers of a shade of apricot. *H. Aureole* is a beautiful new variety which is evidently a hybrid between *Dumortierii* and *Middendorffii*. It forms a compact tuft 2ft. high with narrow foliage, and bears on each stem five or more deep glowing orange flowers, the outer segments of which are coloured a rich brown on the outside. It flowers in June. *H. Lemon Queen* is a distinct form with flowers of a lemon yellow colour inside and

tinted bronze on the outside. *H. × luteola* is a hybrid between *H. aurantiaca* and *H. Thunbergii*. It combines the free-blooming qualities of the latter with the vigour of the former parent. The stems reach a height of 4ft. and bear, on the average, five to eight flowers of a pure golden yellow, each flower measuring ½ins. across. The habit of the plant and its flowers vary a great deal, some inclining to one parent while others more nearly resemble the other. It was raised by Messrs. Wallace and Co., and flowers from June to August. W. L.

MICHAELMAS DAISY NOTES

A FEW matter-of-fact notes on some of the 130 to 140 varieties in the rectory garden may be of general interest and possibly a help to those who are thinking of buying for 1924. We have had such a miserable time of wind and rain during their flowering season that we have not had as many visitors as usual to see them—not only have humans been scarce, but, alas! there have been hardly any butterflies. Visitors are a great help. By their pointing out the ones they like and by their comments on those that I tell them are my favourites, I am able to adjust my own opinion from time to time before my final verdict for the season is given in that *ex cathedra* sort of way which we writers are expected to assume when we pose as guides. In my collection there are no *Nova Angliæ* varieties and no *Amellus* varieties, so, of course, none of these will be mentioned.

In the course of my note-taking I decided a system of grouping would be more generally useful than an alphabetical jumble. After all, there is a convenience in seeing "form at a glance." My groups, then, are as follows: 1, earlier-flowering varieties for out of doors; 2, later-flowering varieties for out of doors; 3, small-flowering varieties—all, that is, but the *Novi Belgii*; 4, varieties to use as cut flowers; 5, "stand-out" varieties; 6, new varieties. One last word before I get to business is to say that I call no variety of Michaelmas Daisy blue any more than I would call any Sweet Pea blue. Some doubtless are getting on in that direction, but to call them blue is but to give them a courtesy title, which I for one am not disposed to do.

GROUP 1.—Some of the best earlier varieties for the garden. *Perry's White*, a white that keeps white. *Edith Goodwin*, most floriferous, a pretty shade of bluey mauve. *Feltham Blue*, an old stager, rich blue mauve, with an attractive orange centre, very early. *Pink Perfection*, a

well feathered marvel of branched beauty with heaps of rosy pink flowers when grown on the one-stem principle. *Lavender*, well named. It

THE GIANT ASTER QUEEN OF COLWALL, WITH ONE FLOWER OF THE HUGE *A. AMELLUS* KING GEORGE, ON THE RIGHT.

is a pretty shade of true lavender. Very early, large flower, not over tall. *King of the Belgians* a giant in height; large, semi-double, rosy-toned mauve flowers. *Lady Lloyd*, free blooming, flowers with pink centres, going more rosy towards the circumferences. Medium height. *Rev. C. Nunn*, selected for colour, which is a very blue toned mauve; unfortunately, rather stiff-looking as a plant, as the flowers come in a mass at the top of the stems. *Bees' Blush*, a little too spidery-petalled perhaps, but it is a real pale pink, quite away from rose, and stood out so well that it always caught my eye. *Grey Lady*, a paler-flowered and taller *Lavender* with more spidery petals, early; perhaps both *Lavender* and *Grey Lady* are not wanted together. *Wonder of Colwall*,

very pale blue of mauve—semi-double, rich flow centre. Dainty, a visitor's tip. At the height of its flowering it is a rosy, elongated dome of hundreds of small double flowers; 2½ft. to 3ft. high. Most effective.

GROUP 2.—*Late varieties for out of doors.* Edwin Beckett. Luckily, it is so different it does not put Climax's nose out of joint, but—

words can exaggerate the beauty of this plant as it came to me from Mr. Amos Perry of Enfield. It has a sort of cordifolius look about it. All down its stem it sends out delightfully light-looking branches, which bear a nice sufficiency of pretty pale helio flowers. It lasts a long time in bloom. Climax.—Late, large pale bluey mauve flowers borne somewhat sparsely on the long branching side shoots. This arrangement gave it its outstanding character and charm. Blue Gem.—If I were to break the rule I have laid down for myself I would write "powdery blue" for its colour. In some lights it does look quite blue; very beautiful. Louvain, tall, graceful pink. It has not for some cause which I know not been Louvain's year, but it would take more disappointments than one to make me think less highly of it than I do. Sunset, such a bright little rose; plants about 3½ft. high. Very floriferous and much branched. Mons, a good tree rose; a good companion to Sunset. Brussels, about 4ft.; pretty pale mauve blooms. Cattleya, very taking rosy mauve, spidery, semi-double, about 4ft. high. Very much a lady's flower. October Dawn, dwarf, large heliotrope mauve flowers 2½ins. in diameter, very free. An excellent novelty. Purple Emperor, another dwarf grower, rich red-purple flowers which give one another plenty of room; no colour in the Novi Belgii like it. Heather Glow, large spidery rosy blooms, very late, most attractive, tall, robust. Mrs. H. Morris, a real rich pink, very late. I see my 1922 note says "flowers rather like those of pink Rhodanthé." Sirius, rose, is excellent. Attraction is still bad to beat, and Belgian Queen and Ribston for extra late varieties deserve mention.

GROUP 3.—*Small-flowering other than the Novi Belgii.* Bianca, a diffusus. Grows like a Cedar of Lebanon, the long flat branches covered with pure white blooms. Comeliness, a pretty pale helio. I think a cordifolius, but probably it has some ericoides blood in it. Very good indeed. Height about 3½ft. Little Bo-Peep is somewhat similar, but not quite so taking. Comeliness and the last named are my favourites of the cordifolius-looking varieties. Failing these, try Ideal, a beautiful rosy lavender. Delight and Decorator (early) and Maidenhood (late) are all excellent examples of the ericoides section with white flowers. Esther is a dwarf thin-petalled pink with heath-like foliage; most popular. Blue Star is one of the best pinky mauve ericoides.

GROUP 4.—*Varieties to use for cut flowers.* By way of preface I want to say that the idea in my mind is to point out the varieties that look best when used by themselves, that is, one variety only in one vase, although the combination of a good cordifolius like Ideal or Comeliness with a fair-sized Novi Belgii like Climax or Wonder of Colwall is most effective. Gladys Donellan, a pale Climax with a soft yellow centre. Climax, wonderfully nice as a cut flower. I do not know which I like best, this or Gladys Donellan. Louvain, tall and stately in large vases. Edwin Beckett, very graceful and light. Roddy.—The white circle round the yellow centre and its general colouring make it a gem for small vases. In growth it is similar to Esther, but rather taller. Belgian Queen (deep mauve) is one of the varieties that have flowers more or less bunched at the end of the side stems, but, all the same, it makes a capital cut flower, and when its lateness is taken into

consideration it is distinctly one to have. Cleopatra, after the way of Belgian Queen, but a very pale mauve is A 1. Pioneer, an early pink with a graceful habit and the flowers not too crowded. Ribston, very late, deep rose, more pleasing shade than Brightest and Best.

GROUP 5.—*"Stand-out" varieties.* Climax and Edwin Beckett in the mauves; Pink Perfection, probably the best rose; Comeliness, my favourite cordifolius; Blue Gem, the bluest of the paler bluey mauves; Rev. C. Nunn, the bluest of the darker bluey mauves; Bianca, the best diffusus; Maidenhood, the best ericoides; Grey Lady, a very beautiful French grey—my favourite with spidery petals; Edith Goodwin, a splendid general utility plant of great freedom in flowering; Gladys Donellan, I think so much of having nice cut flowers, this must be included; King of the Belgians, so stately and tall; Sunset, the most beautiful late rosy pink; Ribston, the most taking shade of deep rose; Feltham Blue, so early and so distinct; Purple Emperor, nothing like it in colour, a rich red-pink; Bertha Cubitt, a prim-looking round flower with a raised rounded centre—very striking, but its peculiarity gives it its place; Pioneer, very early and very pink. I limited myself before I started to make the

list to eighteen, and having done it one cannot omit the very much worn remark about there still being some good fish in the sea. Will any reader pull some out?

GROUP 6.—*New varieties.* Queen of Colwall has, I fancy, the largest flowers of any Aster; Little Boy Blue, a disappointment; Purple Emperor, dwarf, but a very rich colour; Pink Perfection, probably the best rose; Acme, immense deep lavender blooms 2½ins. in diameter—a little large for its height; Bijon, a finely proportioned dwarf, not more than 18ins. high here; pretty smart-looking pinky mauve flowers; Maid of Colwall, not worth its A.M., as not one of my six plants keeps the flowers white to the end. All whites should be judged on their last legs or nearly so. Perry's White, too, is a better and a whiter white. Bees' Pink, a real beauty; there are none too many of these pale pinks in commerce. October Dawn, fine colour and free flowering, dwarfish. Mauve Beauty, shapely flowers of a pretty mauve-pink. Heather Glow, large, spidery, free, late, rosy and most attractive.

I end with an apology to the doubles. I own I have passed them by on the other side, but they are, I am sure, sufficient "sports" to spurn insincere soft soap.

JOSEPH JACOB.

ALPINES FROM THE PASS OF MONT CENIS

(Continued from page 642.)

PLANS for visiting the "higher" parts were seriously interfered with through the operations of the military, who seemed to be extremely active during the whole of my stay in the district. They were a disturbing element from the early hours of each day (5 a.m.) when the mountain artillery calvalcade passed my window, consisting of officers and soldiers with their mules, loaded up with "gun parts" from which they were later on going to pour out shell and shrapnel

into the quiet abode of Eritrichium and other choice alpinists—and it was no place even for an alpine enthusiast. However, we found that operations usually ceased about 11.30 a.m., so that the earlier part of the day was spent in examining the plants around the lake, working as near to the sentries as they would permit, and thus being ready to make the best of the time left to get on to the higher ground after the "aerial fireworks" display, which signified that firing was to cease for the day. In these

MONT CENIS LAKE.

In the foreground the quartz outcrop noted for its rich flora.

waiting periods *Orchis globosa* was seen, fairly abundant on the marshy ground, along with *Orchis latifolia* and quite a nice lot of the lovely *Gentiana bavarica*, one of our most difficult moraine plants—not in moraine here, but in very boggy ground—and the sweet vanilla-scented *Nigritella* with its dark red prominent flower-heads. New paths are being made at a higher level round the lake owing to the lake at the present time being dammed up for the purpose of supplying water and power for generating electricity for the city of Turin, between forty and fifty miles away, and this, apparently, will involve a considerable portion of the lower lying ground being wiped out, along with many interesting plants, owing to the raising of the water level of the lake; in fact, a considerable part has, I understand, already been swamped. Along the banked-up sides of these new paths, where the soil had been disturbed, were some magnificent spikes of *Campanula spicata*, quite a good blue and well proportioned. Unfortunately, it is only an annual. The somewhat singular yellow *C. thyrsoides* was also in evidence in places, and *Saponaria ocymoides* (according to a friend known as "Bouncing Bet" in America) was in beautiful masses of rose-coloured flowers on some parts of the bank sides. The woodier, dwarfer and much rarer *Saponaria lutea* with its pale yellow and not at all striking flowers was also seen on the hill sides above the lake. *Linum alpinum* with its pretty blue flowers fairly frequent, and *Campanula barbata*, one of the best of the alpine meadow "Bluebells," with its delicate pale blue flowers, were prominent. On the dry pasture banks occasional masses of the deep reddish-flowered *Crepis aurea* were very effective, contrasted, as they usually are, with short green grass.

I was anxious to visit the higher ground south of the lake up to the so-called Lago "Fresco" (Farrer). One seems impelled when in the delightful mountain air to get up to the higher parts bordering on the snow, where the visible lives of the plants are so short and where the common Cresses of lower elevations take on an air of distinction in their compactness and have more refined flowers, which makes them almost indistinguishable from the *Androsaces* and other aristocratic companions. It being very wet and the prospect of improvement not very promising, my companions were not keen on venturing into the upper regions, but my time being limited, and as there is always a chance of weather conditions becoming worse in the mountains, I was determined to make the attempt, and my companions agreed to chance it. In recent years considerable numbers of military mule paths have been constructed in all directions in the frontier mountains. This makes it somewhat difficult to hit off the proper tracks, and the Italian Ordnance sheets are not of great assistance, as the military tracks are not indicated thereon. However, we hit off the direction very well, although we did not know with certainty until two days later, as on this, the first outing, we failed to reach the desired lake, although we were within a very few minutes' walk when we turned back, owing to our timekeeper pressing upon us the fact that it was time to make tracks if we wished to be back at our quarters in reasonable time. On the earlier part of the route, mounds of *Silene acaulis* were seen, in some cases covered with their beautiful rose-coloured flowers, others only sparsely covered with the deep green cushion as a pleasant foil. This species was especially fine all over this district and very variable, the flowers in some cases being on lengthy stems and of large size, while others were "squat" on the hard and very compact plants. This form known as var. *exscapa* was more noticeable at

the higher levels, although not confined to them, nor does it take the place altogether at the high levels of the stemmed forms, some of the finest of the latter being seen well on to 8,000ft. up.

(To be continued).

TWELVE GOOD PLANTS FOR THE ALPINE HOUSE

THE alpine house should afford endless interest, especially if the plants chosen are rather difficult under ordinary cultivation in the rock garden. Indoors they may be kept near the eye, and their progress and welfare may be seen at a glance; this is particularly necessary and easy during the

This plant, unfortunately, has never been satisfactory in the garden, becoming looser and flowering very sparingly and, in my experience being hardly worth troubling with. T. ASHTON LOFTHOUSE.

flower-spike, ultimately bursting out into delicious soft lavender Primroses, which are greatly enhanced by the rich apricot eyes. Although very partial to moisture at the root, it resents too much water overhead. Firm planting in a good fibrous loam suits it admirably. During the summer it should be given a cool and moist northerly exposure,

GOOD FOR ROCK GARDEN OR ALPINE HOUSE, PRIMULA × PUBESCENS ALBA.

winter months, when work in the open is often impossible. Excellent results may very easily be obtained in growing choice alpinists in pans. The alpine house need not be an elaborate structure. Any well ventilated cold glasshouse quite in the open will answer, but it should not be higher than is really necessary. There is, of course, an immense number of species and varieties suitable for culture under glass, but I am limiting myself to twelve kinds which do particularly well grown as alpine house specimens, which are beautiful and choice and worthy of the extra care afforded them.

PRIMULA ALLIONII.—A really delightful plant and one of the gems of a lovely race. It appreciates a limestone crevice and has a strong objection to wet hanging about its foliage. It may be grown successfully wedged tightly between two pieces of limestone with a root-run into a mixture of limestone chips, leaf-mould and sand. In May it is spangled with large rosy pink blossoms which "sit" closely on the flat and somewhat sticky green rosettes. I believe that, in its natural haunts, the best specimens are to be found in places where the sun's rays cannot strike directly upon the plant, but I have found it to be a good alpine-house plant, even with a due south aspect.

PRIMULA WINTERI is a charming plant for winter flowering. From November onwards, for a month or so, it continues to develop its powdery

otherwise it may fall a victim to red spider, which, indoors, seems to be its greatest enemy.

PRIMULA PUBESCENS ALBA.—This is one of our real Old-English garden plants, and is better known in gardens as *Primula nivalis*. It is splendid grown in the alpine house. In the early weeks of each year it bears clusters of flowers of the purest white, which have a notable fragrance. The plant has, unfortunately, become rather rare, but no doubt there are still a few old cottage gardens which possess it.

DAPHNE PETREA (syn. *D. rupestris*).—This is one of the choicest of the *Daphnes*. Of great rarity and wonderful charm, it is a hard-wooded plant of very slow growth, a plant a few inches through being quite a good specimen. This is another plant that prefers to be wedged between limestone rocks, and it revels in rich well drained soil and a sunny aspect. About May, it clothes itself with a mantle of waxy pink trumpets deliciously scented, which are not likely to escape notice. Plants may be had on their own roots or grafted on the *Mezerion*. In my experience the latter type are most satisfactory.

ANDROSACE HELVETICA.—This is a dainty little treasure which I feel sure benefits by alpine-house treatment. It is far easier under glass to keep its tiny, downy leaves free from excessive wet in winter, which it dislikes so much. It makes a tight little hummock and adorns itself—in fact, smothers itself—with pretty white flowers

in spring. It enjoys a limestone crevice in full sun, and a gritty compost.

ANDROSACE ARACHNOIDEA VAR. **SUPERBA**.—As the name suggests, this plant is a really superb form of *Androsace arachnoidea*, which cropped up in Mr. Clarence Elliott's nursery a few years ago. It has a stronger constitution than the type, and the flowers and silky rosettes are considerably larger and more vigorous. Limestone-scrce mixture and sunshine are its chief requirements.

CAMPANELA ZOYSII.—A perfect treasure and quite an easy doer, the principal difficulty with this plant is to keep it free from the slugs which seem always to be waiting to devour it. I remember only too well putting into sand about seventy cuttings. On the following morning I was horrified to find that not the smallest fragment of the cuttings remained above the surface of the sand. However, these difficulties can be overcome, and then one may await the glory of the flowers when they make their appearance. These are blue, very quaint and tubular, and the curious puckering at the mouth is the most striking feature of the plant, which appreciates an abundance of limestone chips, together with loam and leaf-mould.

CAMPANELA ALLIONI.—We have here a capital plant when well grown. It comes from granitic rocks, but is not a lime-hater; it will, indeed, grow to perfection in limestone scrce, but at the same time, if it is to be grown as a pan specimen, it is well to give it a granite-scrce mixture. Although the plant grows but 2 ins. tall, it bears giant violet bells about 2 ins. in length by 1 in. in diameter. The foliage takes the form of grey-green, strap-shaped leaves, making a rosette from which underground runners are put forth to come to light and form new rosettes.

DRABA IMBRICATA.—This is a most dainty little plant which gives flowers in early spring. In winter each tiny rosette rolls itself into a little brown ball, which on the coming of spring untolds to assist in forming a shining emerald green mat. The flowers are borne in heads on thread-like stems and are of a golden yellow colour. It requires a very gritty compost.

PHYTEUMA COMOSUM.—This is another plant which does best in the alpine house; it is much beloved by slugs, which are far easier to exterminate in the alpine house than on the rock garden. It is perhaps more quaint than pretty—certainly very quaint. Numerous flowers contribute to form a head, each being Indian club-shaped and deepening in colour from cloudy blue at the base to violet at the tip. Being in nature a crevice plant, it is most satisfactory when planted firmly between rocks.

SAXIFRAGA BURSERIANA GLORIA. In spite of new-comers, *Gloria* still remains one of the best of the early-flowering Saxifrages. All alpine enthusiasts are familiar with the splendid snow white blossoms atop of reddish stems, which it produces so freely in the early year. When not in flower its spiny grey cushions are always handsome. A typical limestone scrce mixture is the key to success.

SAXIFRAGA GRISEBACHII WISLEY VARIETY.—This represents a considerable advance on the typical plants. It has a stronger constitution and is, comparatively speaking, an easy doer. More robust than the type in every way, it produces larger grey leathery rosettes and really fine crimson flower-spikes in spring, which grow from 3 ins. to 6 ins. in length and droop very gracefully towards the top. The whole spike, except the grey bracts, is covered with rich crimson silky hairs. After flowering the rosette breaks up readily into three or four new rosettes which carry the next crop of flowers. It also seeds readily and is a lime-lover.

F. BARKER.

AN AUTUMN VISIT TO WISLEY

A REALLY fine day in November, a fresh wind and a warm sun, a treat after the many dull days that have been the rule of late, and I find myself in the neighbourhood of the gardens of the Royal Horticultural Society, often the end of my pilgrimages, and during the years of the war a temporary home and a haven of peace to me and mine. What if it is wet under foot and the roads newly metalled and thickly creamed with yellow mud, we must see once again this garden of many memories, some of them sad ones but more that are happy, and although one of the companions of those days is no longer with us, her memory will still make those spots the dearer to those of us that remain.

To get the most out of these gardens one must visit them often and see them at all seasons and in all weathers that permit one to remain in the open. A cursory walk through from end to end will leave no lasting impression upon the mind. There is nothing spectacular about the grounds, but there is a quiet charm that is captured only after closer acquaintance, and a charm that is absent in most other gardens that I know—and I am familiar with a good many in various parts of the world. Yet I fear me that much of this is lost to the casual visitor unless someone in real sympathy with the spot, and able to convey his feeling, be his guide; hence no doubt the adverse criticism one hears here and there of people who had heard wondrous tales of the spot and its charms and came and found them not. There is too much to see and the grounds are too wide to judge the whole, or part, after a single visit. The place must be explored again and again before its real charm is captured, and once it has revealed itself to you you will never be able to be anywhere within a few miles of it but it will draw you as it draws me and others, and on each visit you will discover beauties that had eluded you before. On this occasion our time was limited. Three and a half miles there and the same back left us little more than an hour to revisit old favourite spots and discover fresh revelations, and so we restricted ourselves to the part where the floral trials are held, the newly laid out seven acres, the wild garden and the rock garden, and here are some of the features or individual plants that claimed our attention, even so late in the season, and cheered us on our weary trudge towards the distant station from whence we were to return to our still more distant home.

We approached the gardens by the unofficial entrance from the footpath leading to Ockham Mills and, crossing the Pinetum, emerged upon the seven-acre field with its new lily pond and new plantations of ornamental trees and shrubs, many of them fresh introductions from far-away China and Tibet; but this part is too new to hold us for long at this time of year, though, no doubt, next spring or early summer it will claim our critical attention if fate brings us that way, for, unluckily, we are not entire masters of our time and cannot always choose where we would spend our leisure.

The Azalea Garden next claimed us, and I hope to be forgiven for continuing the older name instead of speaking of *Rhododendrons*, as I well know they are nowadays, but I wish to avoid confusion, and some of my readers might think I was referring to the part of the wild garden devoted to these plants. Well, the autumn glory of the Azaleas was a thing of the past, only here and there lingered a brilliant leaf, witness of past splendours; but we came to see what the new Barberries and the wonderful range of hybrids

that originated at Wisley were doing this season, and amply were we repaid. *B. polyantha* and its seedlings could scarcely be finer, and seemed likely to last in full beauty for some time to come; indeed, one form in particular was extra late and not likely to be in full beauty for a week or two. *B. rubro-stilla*, a Wisley creation, is truly marvellously beautiful, and bears out all its early promise and more. It is one of the plants that rouses a feeling of covetousness in me, and I should have found difficulty in refraining from annexing a few berries if there was a chance of it coming true from seed. Knowing this to be hopeless I remained virtuous and hope that at next distribution time the ballot will be kind and bring me a packet of its seed. I saw some time ago a seedling of that plant, raised by an amateur, that was a worthy offspring of so beautiful a parent. *B. Wilsonae*, too, bore a heavy crop of berries and *B. Vilmoriniana* was most attractive in its rich dress of highly coloured foliage. There was a host of *Cotoneasters*, too, in that part of more than passing interest, teaching a lesson of what to use to extend the period of beauty in our gardens until late in the season.

A little further on we came upon a *Hypericum* that was new to us. It still carried, on the ends of gracefully arching shoots, fairly large soft yellow flowers, mostly in clusters of three. The branching was similar to that seen in *Cotoneaster horizontalis*; this was labelled *H. uralum*. I have looked this up since in Mr. Bean's fine work and note that this plant was introduced over a hundred years ago from Nepal. I had rashly concluded that it came from the Ural, as the name suggested, but find it is derived from its native name, "*Urala swa*." If it always continues to flower so late I should call it distinctly an acquisition and wonder it is not seen more often. Under a large Weeping Cherry were great masses of Mrs. Berkeley's very fine strain of *Polyanthus Primroses* that should be worth close inspection next spring. An old friend of ours in the woodland, *Liquidambar styraciflua*, still retained sufficient of its glorious autumn foliage to draw one's attention from the rich golden brown of the dying tresses of the Royal Fern, and near by some large bushes of American species of *Vacciniums* were startling in the richness of their autumn leaves.

A little further on we noted a good contrast in *Cedrus atlantica glauca* ear a greenish golden *Cupressus* that appeared particularly happy under the lighting of the sunrays slanting through the bare branches of deciduous trees. There were late blooms lingering on *St. Dabeoc's Heaths* and on various other Heathers. Along the south-facing border by the series of lily pools the *Cistus*es scented the air with their keen fragrance, and *Nerine Bowdeni* still carried a handsome head of flowers. Having passed through districts where autumn frosts had cut down all that was perishable in plant life, it came as a surprise to see the giant leaves of the *Gunneras* still untouched here in a damp hollow where early and sharp frosts are the rule rather than the exception, and a *Pampas Grass* with truly astounding plumes against a background of the common Japanese Bamboo was a picture that will linger in one's mind as a useful object-lesson for the placing of this decorative plant. Turning into the rock garden we were reminded of the possibilities of *Viburnum Carlesii* clothed in handsomely tinted leaves which, in addition to the sweetly scented flowers it carries so freely in the spring, give it a doubled value in the garden. *Euonymus latifolius*, judging by a few remaining leaves and fruits, must have been a sight for the gods; this is a

plant that might be used much more frequently. *Abelia rupestris* (*A. sinensis*) is much harder than most gardeners realise and, being still full of flowers, should be noted by intending planters. On a bank above the bog was a fine plant of the rather uncommon *Primula megacalyfolia*, introduced years ago by Miss Willmott and found a bad doer in most gardens, in full bloom, and really at this season one has to be super-critical to find fault with its colouring. There were also belated tiers of flowers on odd plants of *P. japonica*, and the *Veronicas cataractæ* and Miss Willmott's form of the false *V. lidwellii* were simply covered with fine white and mauve flowers respectively. A small plant of *Oxydendron arborescens* was a glowing mass of intense crimson and should be used wherever the soil is suitable. Peat and moisture would seem to be essential for this. *Eucryphia pinnatifolia* was a pyramid of glistening golden brown, and recalled to the mind the time when we had admired the tree covered with the exquisite white flowers in the days of the past. *Primula juliae*, which has given us such a host of good, bad and indifferent hybrid offspring since its comparatively recent introduction, was making a great effort of giving an autumn display, and a group of *Schizostylis corceia* associated rather cleverly with *Sisyrinchium convolutum* provided a striking combination. There were still a few flowers lingering on the double white form of *Colchicum autumnale*, a rare plant in gardens, yet of the easiest cultivation and with a long season of beauty. One can only suppose that the plant is unknown to the majority of garden lovers to account for its scarcity. *Verbena radicans*, a ramper, to be introduced with circumspection, and then only where ample space is available, gave a very handsome account of itself. I believe this to be the hardiest of the creeping *Verbenas* one sees nowadays quite commonly in rock gardens, and, personally, I prefer its presence to that of the intense *V. chamædrysoides*, which has such an awful bedding-out look about it somehow. Another plant to be used with care was *Hieracium rubrum*, which flaunted some late but richly coloured blooms. I believe it to be a little less fecund "Grim the Collier," *H. aurantiacum*, but I know I should watch it carefully in my own place and remove the flowers before ripe seeds are formed.

There were two good patches of *Gentiana sinuata* doing their best to continue a display that must have been fine a short time ago, and *Primula Winteri*, that is so entirely happy at Wisley at the foot of a north-facing cliff, where I have known it for several years, was opening the first of its charming flowers and gave ample promise of continuing its display for months to come. This plant, reputedly difficult, is not really so if the right place and conditions are found for it, and a study of this at Wisley should lead to better success in other gardens. *Wulfenia ambergiana*, comparatively rare in gardens, was still in flower, and is more attractive than its European relative, being so much more graceful.

A hurried glance into the alpine house concluded our visit. *Saxifraga Kellereri*, always the earliest of the hybrid *Kabschias*, was on the point of opening its flowers. *Sedum Palmeri*, that is so much more hardy than it looks, carried fine golden flowers, and *Saxifraga Fortunei* bore aloft panicles of its uneven petalled white flowers. *Parochetus communis*, of which Wisley boasts two distinct forms, were each represented by a good pan carrying a few of the pretty blue pea flowers. I had recently seen this plant in a Sussex seaside garden, where it evidently intended to continue to bloom right through the winter, as it will when really happy. I am inclined to think that the form raised at Wisley, which has

a more hairy leaf and a slightly crenulated leaf margin, carries the finer flower and seems better adapted to survive our winters. *Saxifraga Balfouriana*, with yellow flowers, is of considerable interest, but will, I fear, never become a popular

plant in our gardens. Hybrids of *Primula juliae* were just opening early flowers, and there were many fine pans of good plants giving promise of a charming display after the turn of the year. W. E. TH. L.

CORRESPONDENCE

QUERCUS ILEX AS A SEASIDE PLANT.

IN THE GARDEN for November 10, your correspondent, "Z," in dealing with plants suitable for "Windswept Seaside Gardens," seems to be in doubt as to the suitability of *Quercus ilex* (Evergreen Oak) for such a position. As your correspondent invites information from the experience of others on the subject generally, I beg to give my experience with this one tree. A few yards from where I write—on the southern shore of the Firth of Forth, e.g., at Musselburgh—is an aged specimen which has year in, year out borne the full

THE LAVENDER WALK.

A LAVENDER walk is a garden in itself, admired by everyone. Even a sprig of this fragrant plant is appreciated, but to be able to walk through it is pleasant indeed. In a large garden the lavender walk may be used as a division between one garden and another, as in the accompanying picture of the one at Oxted Place, where the lavender walk divides the rock garden from the rose garden. The walk is about 100ft. long, and the path itself 6ft. wide between the lavender. A wide grass path is preferable, as it is easier for mowing. To obtain enough plants for such a walk is not a very expensive item, as one

THE LAVENDER WALK AT OXTED PLACE.

blast of the north-east wind coming right up the Firth from the North Sea. The tree, which has a clear bole of about 12ft., has an umbrella top of clean, healthy foliage although the leaves are not such a bright green as those on four noble specimens in a mausoleum garden about a hundred yards distant. This quartet, although not in "the first line of defence," get a good sweep of the wind from the Firth, which is always more or less salt-laden. They vary in height from 15ft. to 25ft., and are of bush form, with a spread of from 12ft. to 15ft. The dark glossy green foliage is spotless. I agree with "Z" however, as a result of forty years experience that, planted where things are expected to be kept tidy, they are very tiresome, because, like evergreens in general, they go on dropping their dead leaves throughout the summer, and these, half curled up and with sharp edges, stick to grass and gravel (especially grass), like limpets to rocks, so that it is most difficult to sweep them up.—CHAS. COMFORT.

fair-sized plant will produce enough cuttings to go a very long way. The method I find best is to root the cuttings in spring in a cold frame and plant them out about 2ft. apart the following autumn; they will then form nice plants by the following summer. The plants should be cut hard immediately the bloom has died off, to prevent their getting bare at the base and to keep them shapely. The old-fashioned lavender is now supplanted by the variety *Grappenhall Variety*, which is more vigorous in growth and constitution, blooms more freely and is hardier. There is also a white form, *Lavandula spica alba*, but it is not so free. The dwarf varieties are excellent for some purposes, the two best being called *atropurpurea nana* and *Munstead Variety*.—R. C. JOLLIFFE.

WEeping STANDARD ROSES.

I WELCOME the article on "Weeping Standard Roses," and wish it had been published two months ago. May I say however that although

I have tried Paul's Scarlet as a weeper and found it refractory. I have, on the other hand, no fault to find with American Pillar. I have had one ten years which is everything that a weeping standard Rose should be. I wonder why growers confine their lists to such a few varieties. I tried to get Sanders' White this autumn, but was not successful.—(Mrs.) C. F. T. WOLLERSEN.

A CURIOUS MALFORMATION.

THIS Savoy Cabbage, of which I enclose a picture, was found growing among a batch in an allotment garden on the outskirts of London, and formed a perfectly shaped gramophone horn. These queer freaks of Nature are, so many authorities believe, generally caused through injury to the plant when quite young. Such fasciated growths are very rarely seen among the Brassica family. They are more frequent among herbaceous plants, particularly Delphiniums, also among trees and shrubs. They generally take the form of a wide flat stem. It is best always to cut these growths out of plants, as they are never any good and look unsightly—except when they take the growing gramophone horns!—H. C.

A PICTURE IN BLUE AND GREY.

A BORDER which looked particularly attractive here last season was planted almost entirely with Larkspurs and Nepeta Mussinii. There were, though, two other kinds used, each having its own distinctive charm in helping to create the desired general effect. These were bushes of Lavender and the lovely blue annual, Phacelia campanularia. Two varieties of Larkspurs were used, namely, the tall stock-flowered blue and the mauve-toned one. These were chiefly employed in bold masses at regular intervals where the rather long border widened somewhat. The narrower stretches had a good row of Lavender in the background, with Nepeta and Phacelia in front of it. Looked at from either end, and, I think, more particularly towards evening, the picture was a pleasing one, and the length of border, about a quarter of a mile, enhanced it. Those interested in any such colour arrangements who may not have tried the above will, I think, find this worthy of their notice.—HENRY TURNER, *Albury Park, Guildford*.

NOVEMBER ROSES.

ROSES have done very well here this year; flowers have been fine and plentiful, and the foliage fresh and clean. The winter of 1922-23 was remarkably mild, and I gathered Roses in profusion throughout December and January, the last bunch of last season being gathered in February, 1923! The flowering was only ended eventually by severe spring pruning, but, all the same, the plants have shown no sign of exhaustion and have flowered this summer as well as they have ever done. The following is a list and description of a few varieties which are particularly noticeable at the end of November: Mme. Segond-Weber.—Produces beautiful buds and is good to cut at any stage. The flowers hold their heads up and are carried on stout stalks. Hugh Dickson is full of buds. It has dark green foliage, which looks very well with the crimson flowers. Antoine Rivoire.—In October I cut one single

stem with twenty expanded blooms! It is a delicate ivory colour shaded with pink, and throws fine flowers now and throughout the season. The foliage is very healthy and the stalks red. Countess of Hebe.—A bright pink variety which produces masses of buds. There are thirty-five on one stem at the time of writing, twenty-one on another. Triumph.—A little-known Rose and one of the very best, this has a perfectly erect habit and an inexhaustible supply of bloom. The colour is a beautiful crimson which does not fade or turn blue in the sun. Indeed, it is of much the same colouring as Liberty,

A CURIOUSLY FASCIATED SAVOY LEAF.

but a better Rose in every way. The foliage is very good and it is full of flower now and has been throughout the summer. It is sweet scented. Entente Cordiale (Hybrid Tea).—Not so strong as some, this forms a beautiful bud. It is free to flower and pale ivory yellow in colour. We have kept no record of the date when these Rose trees were planted beyond the fact that it was before the war.

Climate and soil vary, of course, so much in different parts of the country that a system which suits our garden may easily fail elsewhere. We find "summer" pruning improves the second blooming enormously. As soon as the last flower on a stem is faded we prune the stem immediately hard back to a leaf bud which shows some sign of movement. This may be anywhere on the stem, the lower the better. Practically all these pruned stems will eventually produce flowers. The summer pruning removes also all the weak, useless young wood, leaving only the strongest young shoots of the year coming up from the ground and, unhindered by the greedy exhausted flower-bearers, they grow with remarkable vigour, producing the fine heads of flower mentioned above.

I should like to add that, of course, I do not consider very late autumn—or winter—the ideal time for judging the merits of the different varieties of Roses! Some of the old favourites are doubtless still to be found basking their own here on a summer's day, but I do think that late autumn beauty is a great virtue in a Rose.—RUTH BICKERSTETH, *Cottingham, East Yorks*.

EARLY CHRYSANTHEMUM ALMIRANTE.

IT is what a person grows for his own use, either for garden decoration or for cutting, that, more than anything else, gives us an indication of what he considers the best "practical politics" plants. It was a veritable pat on the back that Mr. Crane undesignedly gave me when I read his remarks about Almirante in THE GARDEN of December 1, when he was writing about the trials at Wisley. In the days before Marie Massé I used to have a fair number, but since its appearance I have been out of touch with named varieties, for a packet or two of seed from Sutton's has amply provided for my wants and saved us all the bother of taking cuttings, because we grow the plants as annuals. However, when I was at Myddelton House this autumn I made a special note of Almirante and told my host how much I liked it. "Yes," said Mr. Bowles, "one of the very best." Now, my good friend, when you get him away from Crocuses and "the lunatic asylum," is, in a way, like us ordinary people, only that we have to remember that his sharp eye has seen pretty well all that is to be seen in English gardens of hardy plants. Thus praise from him is praise indeed. Backed with the imprimaturs of Messrs. Bowles and Crane I do not think I am far out of it when I advise those who do not know it to give this beautiful early-flowering variety a trial in 1924.—J. J.

PAPAVER UMBROSUM.

SOME annual flowers are so free in their self-sowing of readily germinating seeds that they are for many purposes equal to perennials, except that the seedlings do not always come where they are wanted. Among these I always place Papaver umbrosum, referred by the "Index Kewensis" to P. Rhoeas, the Corn Poppy, but generally considered by gardeners as distinct enough to retain its specific name. That it is so useful that it may almost be called perennial is a statement supported by the writer's experience. It must be more than twenty years since it was first grown in my garden, and no seed beyond the first packet has ever been purchased or has ever been given to me, nor have I ever saved seeds for my own sowing. Yet with the exception of a year or two I have had plants of P. umbrosum in flower throughout the intervening years. The exception was caused by a disastrous spring frost which destroyed every seedling annual Poppy in the garden, together with seedlings of Limnanthes, Nemophila and almost every hardy annual and biennial in the place. In a year or two, however, seedlings of P. umbrosum appeared from seeds which must have been turned up nearer the surface and which had escaped the massacre of the others. This is, I consider, a good record for Papaver umbrosum, which has beauty of the highest order, with its pretty leaves and brilliant, deep crimson flowers with their well defined black blotches on plants not more than 18ins. high and frequently less. The best plants are from self-sown seedlings which are left to bloom where they spring, but seeds sown at the usual season for hardy annuals will bloom the same year, though not giving such good plants. The seedlings ought to be well thinned out—to 1ft. or so apart at least.—S. ARNOTT.

FORTHCOMING EVENTS.

December 18.—Sevenoaks Gardeners' Chrysanthemum Society's Meeting.—Winchester Horticultural Society's Meeting.

December 22.—Dunfermline Horticultural Society's Annual Meeting.

SOME HINTS ON THE CULTIVATION OF SEAKALE

SEAKALE is universally appreciated and its culture very simple. Yet one meets with many gardeners, both amateur and professional, whose knowledge of its requirements is very imperfect, judging by questions put when they see a plot of several hundred crowns growing. Often they try to excuse themselves on the ground that they have no proper place provided for forcing. Neither have I, but I force annually never fewer than 400 crowns. We have a good range of glass-houses, and gardeners, quite naturally, think that a proper forcing-house has been provided for such crops. It is true there was one, but places change hands and new owners often change the place—not always to its improvement. Here, at any rate, the mushroom and forcing house was converted to other uses many years since and its heating apparatus ruined, so that its chance of being ever restored to its first use is very slight. Many have expressed great surprise when shewn the simple means by which the supply of Seakale has been provided over more than three months in the year.

Under a large stepped stage in a three-quarter span greenhouse they see two large packing cases measuring inside 25ins. in length, 22ins. in width and 18ins. deep. Each will accommodate six dozen crowns. The covers and joints are made quite light-tight, and to protect them from drip a covering of waterproof roofing material is used. They stand on tiles placed on a 4in. flow and return pipe where a gentle warmth can be maintained. Five inches of sandy soil is deep enough, and while forcing is going on this should always be kept in a moist condition. Never allow it to become dry or soddened with water; both extremes do much harm. Other makeshift methods will occur to those who are really determined to succeed, and the rules to be observed are the same in all cases. Introduce only as many crowns as are strictly necessary in each batch at intervals of about a week or so. As soon as the heads are ready use them quickly, as from this point the quality rapidly deteriorates. Gentle forcing gives the best results, so try to strike the happy medium as regards heat and be careful with the watering. Whatever the means adopted, all light must be absolutely excluded or the produce will be purple instead of white.

Seakale is propagated by seed and root cuttings, which are known as sets. The best are made from roots of half an inch and upwards in diameter. The length of sets varies, but I prefer them about 4½ins. The upper end is cut off level and the lower slantwise, this to prevent a mistake at planting-time, as, of course, buds grow only on the upper end of the root. Those commencing the cultivation of Seakale invariably find it difficult to buy sets. Instead of sets the trade growers usually offer only the crowns which are too small for forcing—poor, weakly things which lacked the vigour necessary to grow into a root of forcing size. One sees them offered for sale in seedsmen's catalogues as "third size roots, good for planting." Are they? I think the unsatisfactory state of many a little plot of Seakale could be traced to the use of these mis-called "good planting roots." If one is compelled to "chance it" with these, see that the prominent bud is cut clean away—this to prevent formation of flowering-stems. I would advise, too, a sowing of seed at the same time, thus providing another string to the bow. The only objection to the use of

seed is the loss of a year in growing a good crown as compared with the root-cutting or set.

The cultivation of Seakale, whether from seed or sets, for annual lifting or permanent plot, should be on the most generous scale which can be afforded. The spot chosen for either should be open and sunny and deeply worked, with plenty of manure

Liberal soakings of liquid manure will be appreciated right through the summer. Procure sets if possible, or if unprocureable, roots in good time; if the latter, cut away the bud and stand them loosely on end in a box slightly deeper than the sets or roots and fill in with sand level with the tops. Place the box in a light cool place and keep them moist. Here they will callus and buds will form. If, as the season advances, they shew signs of making growth, remove them to a cold frame or even the north side of a wall, it being much better to have only buds at planting

DIGGING THE SEAKALE AND TRENCHING SIMULTANEOUSLY.

PREPARING THE SETS FOR PLANTING.

or material from the rot-pit or heap incorporated with the lower spit. Salt is very beneficial to the crop, and dressings of roz. per square yard may be given two or three times during the summer or before the foliage has met across the rows. If growth is slow, nitrate of soda is a good stimulant, so is good guano or fowls' droppings, all to be well hoed and if the weather is dry watered in.

time than to risk having tender growths cut down by bad weather.

If the sets are put outside to retard growth, the tops of the sets should be protected by adding extra sand, otherwise slugs may do much damage. Many growers just bury the sets in sand or sandy soil until planting-time, but I find a great advantage in boxing them and making sure of a good

inside. A quite small box will take 500 sets. Planting may be done from the middle of March to middle of April. The roots are hardy enough, of course, to be planted at any time during winter, but slugs, especially, can do much damage to them, and planting slightly started sets in spring is preferable. Thinning of the growths should be attended to in good time, as several growths may start from each root, and these should be reduced to one, the strongest. For the finest crowns, with liberal cultivation, the sets may be planted 18 ins. apart in rows 2 ft. 6 in. asunder, but good serviceable crowns can be grown 1 ft. apart and 2 ft. between the rows. For the permanent bed, to ensure a fuller crop the first season, the sets may be planted in groups of three well inside the circumference of the pot to be used for blanching, allowing not less than 3 ft. between the groups. When our crop is lifted for forcing, which is begun as soon as the foliage dies down or is cut down by frost—or if growth continues late in a mild season, a few roots may be dug and exposed to the weather to give them a check preparatory to forcing—the plot is measured off exactly as for bastard trenching and the top spit from the first trench deposited near where the work will end. The worker has a basket, and as each root is lifted bodily out he will break off all the best roots to be used for sets, and these he will lay at one end of the basket with the upper ends together. The crowns will go in the middle and the small waste portions of roots at the other end, and thence to the garden fire as the basket fills. The selected roots are stored in a shed to be made into sets during bad weather, and the

crowns are heeled in thickly on the north side of a wall in sand or sandy soil to be used for forcing as required. When the first trench is clear the bottom spit is well dug and any remaining roots cleared out and manure added. Thus during one operation the plot is deeply dug, thoroughly cleared of roots and manured and the top spit thrown up into ridges for the winter. If necessary, the same plot may be used for Seakale year after year. Set-making is simplified by having the roots selected and laid ready as dug, it takes no more time and is a great improvement upon the

SEAKALE FORCED IN A PACKING CASE.

method many use of throwing all the roots together, having subsequently to sort them out again. When the sets are made, a brick is placed on the bench 4 ins. from the edge and a supply of roots laid near to the operator's hand. He will take a root and with a sharp knife cut the upper end squarely across, place it against the stop and cut it through slantwise at the edge of the bench, and in this way a few hundred sets are accurately made in little time. H. C. W.

A GARDEN NOTE BOOK

SIR HERBERT MAXWELL is a charming writer who knows more about gardening than most men, but makes no pretence to knowing everything; indeed, in this book* he very frankly confesses his limitations. The scope of the book may partly be gathered by the titles of the chapters; these are: Some Hardy Bulbs, The Herbaceous Border, Some Flowering Shrubs, Some Rhododendrons, Wild Gardening, The Choice of Plants, Some Plants for Walls, Rockwork and Edgings, Some Failures, Some Weeds, and Some Plant Names. The spirit of the man comes very clearly forth in a passage such as this: "Truth to tell, my heart goes out far more readily to a natural species and its spontaneous varieties than to the more showy, but often coarser, manipulated products of the florist. . . . The primary merit of a flower is its appeal to human perception being beauty, none of the myriad forms into which the Magni-Coronati or Trumpet Section of Narcissus has been coaxed can be deemed to excel our common wild Daffodil, *N. pseudo-narcissus*, and its natural

varieties, bicolor, minor and minimus. Nevertheless, the most exclusive collection should also embrace *N. Johnstoni* Queen of Spain, reputed to be a natural hybrid between *N. bicolor* and *triandrus*, originating in the mountains of Portugal." This is a spirit with which the reviewer sympathises very strongly, though it is necessary to point out that the majority of gardeners would not, but the particular instance selected does not seem a very fortunate one, for the Lent Lily is not a specially gracious or attractive wildling.

After the extract given above no one will expect to find in these chapters lists of the best florists' varieties. There are, however, plenty of books to give such guidance, whereas there is but one Herbert Maxwell, and he gives first-hand information which is often of the utmost value; for instance: "Anyone who has seen the meadows at Lilley, near Oxford, in late April, or those near Azay-le-Rideau in Touraine earlier in that month, crowded with the chequered bells of the Common Fritillary *Fritillaria meleagris*, may well have wondered why such a choice display has not been prepared in other districts. There is only one hindrance to doing so, for the plants, once established, increase rapidly by seed. That hindrance exists in that child of Belial—the rabbit."

Extremely helpful and pertinent is the advice Sir Herbert gives about Lilies, while of his beloved Rhododendrons and such choice shrubs as the *Eurythias*, the *Desfontainea*, the *Ceanothus* and *Buddleia Colvilei* he writes with justifiable enthusiasm and absolute knowledge. Not every garden writer has the courage to pen a chapter on failures, yet this is one of the most helpful chapters in the book. The weeds to which reference is made in the penultimate chapter are plants beautiful in themselves and deliberately introduced, but which prove themselves an intolerable nuisance in the garden.

The last chapter, it may be remembered, is about plant names, which brings to mind that Sir Herbert appears to have unorthodox views about the use of "capitals" for specific names. Thus he does not employ the capital for old generic names now degraded nor for generic names borrowed from the animal kingdom (he writes *Cypripedium calceolus* and *Fritillaria meleagris*), but he employs capitals indiscriminately for species named after people and after localities. Thus he writes of "*Primula Japonica*," *Rhododendron Sutchuenense* and *Piptanthus Nepalensis*. This, it is to be feared, will trouble more orthodox botanists, though it is evidently deliberate, but the book shews evidence of hasty proof-reading. There are more slips than there should be in a work of this character, especially in the case of specific names in the Genitive case, thus we find "Fargesii" for "Fargesii" and so forth. More serious, perhaps, are *Aubretia* (constantly) for *Aubrietia* and *Penstemon* for *Pentstemon*. In one place there is a singular miscalculation. Sir Herbert is comparing the growth of Shirley Poppies at 4 ins. apart each way and 1 ft. each way, and says that in the former case there will be three times as many as in the latter. Oddly enough, he elaborates the idea without noticing the slip, and states that whereas in the one case there will be thirty-six plants in a patch 6 ft. square, there will in the other case be 108! The printer's reader should surely have noticed a slip such as that.

On the whole, however, the blemishes are like the beauty-patches of the days of powdered hair—they only serve to bring into relief the many good points of the book, which include, in addition to the excellent matter, splendid printing on good paper and twelve beautiful plates in colour depicting *Eucryphia pinnatifolia*, *Lilium regale*, *L. Brownii*, *Cypripedium calceolus*, *Meconopsis simplicifolia* Baileyi, *Helicodiceros crinitus*, *Desfontainea spinosa*, *Ceanothus puniceus*, *Buddleia Colvilei*, *Rhododendron Souliei*, *Alstroemeria Hookeri* and *Prionia Cambessedosi*.

R. V. G. W.

Gardening of the Week

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Potatoes.—Make periodical examinations of the tubers in store and promptly remove all diseased ones. Keep the shed as cool and airy as possible, but the tubers should be protected from frosts. The "seed" of the early varieties may be set up in trays or boxes and the main crop spread out thinly on the floor. These need not be covered, but light should be excluded from those intended for the kitchen.

Rhubarb and Seakale.—To keep up a supply more roots should be introduced to gentle heat, and at this season both will force more readily than a few weeks ago if the roots have been lifted and exposed.

Mint.—This is always in demand, and roots may be lifted, placed closely together in boxes containing light soil, and then covered with an inch or so of old potting compost. Gentle forcing with a temperature not exceeding 50° will give the best results.

* "Flowers: A Garden Note Book," by the Right Hon. Sir Herbert Maxwell, Bart., F.R.S., LL.D., D.C.L., V.M.H. 16 + 250 pages, 4to. Published by Messrs. MacLehose Jackson, and Co., 73, West George Street, Glasgow. Price 25s. net.

Parsley.—Plants in the open are still producing a good supply, but it is necessary from time to time to pick off all the dead and decaying leaves, and when the soil is dry enough it may be lightly hoed over or pricked up with a fork. We rarely get much snow in this district, but if there is any likelihood of it coming, the parsley-bed should be covered with a few mats; then the snow can easily be removed. Plants in frames or pits should be kept as cool as possible or growth will be weak.

Carrots.—Where early young Carrots are appreciated and the necessary facilities exist, a sowing of an early Horn variety may be made. Brick pits are advised, the base of which should be filled with leaves, well trodden in and brought up to within 2ft. of the lights. A layer of rich soil to the depth of 5ins. will be required, and the seed, which should be sown broadcast, covered with a thin layer of finely sifted soil. If the soil is fairly moist, no water will be needed until germination has taken place.

The Flower Garden.

Iris stylosa.—Slugs are very partial to the buds of this beautiful Iris, but a sprinkling of lime, Slugs or soot around the plants will ward off this destructive pest. The flowers should be cut in the bud stage, and if placed in a warm room or greenhouse they soon expand, and are excellent for decoration.

General Work.—At this season any alterations or improvements should be proceeded with and completed as soon as possible. With the arrival of the New Year the days soon begin to lengthen, and other important work will need attention, hence the necessity for pushing on with the regravelling of walks and drives, filling up holes and repairing bad patches on lawns, and trimming of verges. Box edgings may be made tidy and gaps filled by lifting a portion of the plants and dividing them. Lawn-tennis nets should be overhauled and repaired when the weather is wet, and garden seats, etc., painted. Drains should be put in order and new ones made where needed. All walks and paths should be well rolled after frosts, but if lawns are rolled it should not be when they are in a very wet condition.

The Rock Garden.—Many rock gardens are situated near large trees and, if not already done, fallen leaves should be collected, otherwise some of the plants may decay. Set traps for slugs, and see that the plants are correctly labelled.

The Hardy Fruit Garden.

General Work.—Whenever the weather is favourable, continue to push on with the planting of fruit trees and the root pruning of others where such is considered necessary. Some trees, and especially those growing at the base of walls, may be unproductive and the growth made of an inferior nature. Where such cases exist it is usually advisable to lift the tree, cut away any dead roots and replace some of the old soil with fresh material; at the same time ascertain if the drainage is in order. When replanting make the soil firm and bring the fibrous roots tolerably near the surface. Lime in some form is essential for all stone fruits, and at this season a sprinkling over the soil will be beneficial. The pruning of Apples and Pears should be continued and completed as soon as circumstances permit, the prunings being collected and burnt and the plantation made clean. The fruit-room will require attention from time to time to prevent decaying examples from affecting the sound fruit. There is very little fruit this year, and that from orchard trees is not keeping as well as one would like.

Figs.—If severe weather sets in it will be necessary to protect the trees in some districts or the first crop next year may be light. Mats of the Archangel type make very good protecting material. Trees not overcrowded with sappy young growth and with roots more or less restricted are not so likely to be injured by frosts.

Vegetables Under Glass.

Cucumbers.—Seeds may be sown singly in small pots containing warm light soil and then placed in a warm propagating house. When the seedlings have filled the pots with roots, transfer them to receptacles 5ins. or 6ins. in diameter and grow them in a light position to prevent the growth from becoming weak and spindly. These will make nice plants for planting out in the New Year. Everyday is a good variety, and should be given a trial. T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),

Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

Vegetables Under Glass.

Rhubarb. Introduce a few more stools into moderate heat according to prospective requirements, and lift and expose a few more for future forcing.

Tomatoes. A sowing should now be made in a temperature of about 60° to furnish early supplies. A short jointed, free-setting variety bearing medium-sized fruits, such as Holmes' Supreme or Carter's Sunrise, is most suitable for sowing at this time. It is advisable to sow in pots or an earthenware pan and to use a rather light sandy compost, as damping has to be guarded against.

Lettuces in frames should be fully exposed on all favourable occasions. Stir the soil between the plants with a stick to prevent damping and, should slugs threaten, give a light sprinkling of soot. A partly scooped-out half orange skin slightly tilted on one side is considered to be an excellent slug trap.

Mustard and Cress.—Continue to make sowings every ten days. If sown too thickly these are apt to damp off during the short dull days, but I have found that Brown Mustard is less liable to damp than the white variety. It is unnecessary to cover the seeds at this season. As a matter of fact, some cultivators sow on a wet cloth instead of on soil.

Cauliflowers.—The directions given for Lettuces are also applicable to Cauliflowers.

Fruits Under Glass.

The Early Vinery.—Sufficient fire-heat should now be applied to maintain a minimum temperature of 50°, allowing the thermometer to run up to 60° with sun-heat. Advantage should be taken of every hour of sun-heat, not only with the idea of keeping down the coal bill, but because solar heat is more to the liking of all kinds of vegetation than fire-heat. Damp the pathways morning and evening and lightly spray the rods with tepid water when closing the ventilators for the day.

The Late Vinery.—The pruning of the Vines should no longer be delayed, even if there is still some fruit hanging on them. Evaporation is so slow at this season that if the bunches are cut and hung clear in a cool, dry room they will keep for weeks without shrivelling. Of course, if one cares to take the trouble of bottling them they will keep in good condition for a longer period.

The Early Peach-House.—A start should now be made if an early crop is expected. The Peach being naturally an "early riser" and easily excited into growth, comparatively little forcing is necessary even at this early date. If the house is shut up for a fortnight and is freely ventilated during bright sunshine, a minimum temperature of 45° will be quite sufficient for the next fortnight, at the end of which the trees will probably be opening their flowers, should the weather prove propitious.

The Rock Garden.

Winter Protection.—Some of the choicest rock plants require protection in winter, not to protect them from cold, but from excessive moisture; the reference is to woolly-leaved plants of which the foliage is apt to be injured in our moisture-laden atmosphere. *Androsace sarmientosa* is an example of this type, as well as several other species of the genus. A sheet of glass about a foot square is suitable as a form of protection. These sheets of glass, with the necessary supports provided, may be obtained through any nurseryman or seedsman. At least two forms are on the market, one with a stiff support, the other with a universal hinge which can be adjusted to any angle.

Extensions.—This is a suitable time for making extensions so that things may be in readiness for planting in early spring. In constructing rock-work those who have not had experience of such should note that at least three guiding principles should be observed as essential to the successful cultivation of any class of alpine. First, avoid all appearance of formality both in the general conformation and in the execution of the details; secondly, provide a liberal depth of rooting medium. Novices think because they see a plant luxuriating on the surface of a rock that it is a shallow rooter, oblivious of the fact that its roots extend 5ft. or 6ft. down a fissure of the rock where there is perpetual moisture. Thirdly, each pocket should be so constructed that it will retain its share of

the rainfall, even although recourse may have to be had to the use of a little cement.

The Flower Garden.

Sweet Peas which were sown in autumn in small pots should now be shifted into 5in. pots. Avoid using a rich soil and depend upon fibrous loam with a little sand and a very little bonemeal.

Geraniums.—Examine young stock in boxes and any specimens that were potted up for tilting vases, and remove all decaying leaves; and in the case of the latter cut away any decaying shoots. Keep the plants on the dry side so long as the stems do not shrivel.

Lawns.—On all but clayey soil, worms will be carrying on their beneficial work. Scatter their casts occasionally with the broom and then apply the roller; hush up any turning that has to be done.

CHARLES COMFORT
(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mans, Midlothian).

GREENHOUSE AND CONSERVATORY.

Acorus gramineus variegatus.—This pretty little plant is of neat habit and is useful for growing in small pots for the cool greenhouse. It also makes an excellent permanent edging plant for a bed or border in the conservatory. This plant is easily increased by division in the spring, and grows freely in any good potting compost.

Liriope spicata variegata makes a fine permanent edging plant for beds or borders in the conservatory. If grown in pots it is very useful for decorative work in the dwelling-house. It grows freely in any ordinary potting compost, and should be given perfectly cool treatment at all stages of its cultivation; in fact, it refuses to grow in a warm temperature. For decorative work the most useful examples should be grown in 48-sized pots.

Helxine Solierolii.—This dwarf bright green carpeting plant is very useful for a variety of purposes. It makes an ideal edging for stages, a band some 6ins. wide giving quite a finish to the front of the benches. In such positions it succeeds perfectly on little more than 1in. of soil laid on the bench, placing a few crocks or some gritty material underneath the soil. Small pieces of the plant dibbled into the soil will in a few weeks cover it with a fresh green carpet. However, it will grow almost anywhere, along the edge of paths or underneath the stages. It is also very useful for growing in pots or shallow pans and used for decorative work in the dwelling-house. As it is more or less hardy in the South, it is a very useful plant for the unheated greenhouse.

Iris japonica (syn. *I. chinensis*) is a very pretty plant, and may either be planted out or grown in pans in the cool greenhouse. Its pretty lilac-coloured flowers, which are marked with yellow and white towards their centres, have their edges finely fringed. This Iris flowers during the spring, and although the individual blooms only last a short time, they are so charming that they always appeal to the true plant lover. The plant is evergreen, and is easily increased by division, growing readily in any good potting compost. There is a variety with variegated foliage.

Iris Wattii is of more recent introduction than *I. japonica* and somewhat resembles that species, but has smaller flowers. *Iris Wattii* is a much taller-growing plant, the annual shoots reaching a height of 2ft. to 3ft. The flowers are produced on the ends of these. After flowering, a portion of the shoots should be cut out to give room for the young growth. This plant is very nearly hardy, and is therefore very suitable for the unheated greenhouse.

Lygodiums are climbing Ferns, and most of the species require a warm temperature for their successful cultivation. However, *L. japonicum*, which is the most elegant of them, is perfectly happy in a cool house, and is a fine plant for training up under the roof glass. The long growths, when matured, are ideal for decorative work, and it is surprising that this plant is not more generally grown for this purpose. Good specimens can be grown in 8in. or 10in. pots, but where it is desired to grow it in quantity for cutting it is best planted out in a narrow border or in boxes, training up each shoot separately on fine twine. This Fern grows freely in any good potting compost. Ample drainage should be provided, as this plant enjoys plenty of water at the root during the growing season.

Adiantums that have done service in the dwelling-house or conservatory generally become

slightly at this time, and it is desirable to keep them on the dry side for a while. Early in the New Year before they start into growth they should be shaken out of their pots and repotted, dividing them if necessary. Afterwards start them into growth in a warm, moist house. Water should be applied carefully at the root until the plants have made some fresh growth and got well away from the root. The pots should be well drained. These plants enjoy some old mortar rubble in the potting compost.

Libertias are natives of New Zealand, Australia and Chili, and are more or less hardy in the South and in favoured situations further North. They are, however, excellent plants for the cool conservatory either planted out in beds or borders or grown in pots or pans. Their cultural requirements are not difficult, as they thrive in any good potting compost. They can be increased by careful division or by means of seed, which is best sown when ripe. The most useful species are *L. formosa*, *L. paniculata* and *L. pulchella*.
Royal Botanic Gardens, Kew. J. COULTS.

HOW TO KEEP THE VINE BORDER SWEET

It is well known that deciduous plants require less water in winter than in summer because there is little or no transpiration taking place, but it is a great mistake to keep the soil containing their roots really dry. In a natural state they are in a more moist medium during winter and spring than at any other time, yet it seems to suit them. Healthy plants are never really quite dormant; they must have at least a little water to draw on, although it may be very little indeed that they take up.

The difficulty we have with inside borders arises from the fact that plants are often placed on them which must have a liberal supply of water, and they cannot have this without the surface of the border getting more than is good for it, which causes a growth of moss and lichen and prevents aeration. At the same time the soil below may be really too dry. Now aeration of the soil containing the roots is one of the principal necessities for a plant's health.

Dr. Masters tells us in "Plant Life" that "roots have the power of absorbing the oxygen contained in the soil, and if a supply of oxygen is cut off, the roots will die from suffocation. One use therefore of ploughing and harrowing is to keep the soil open and thus allow access of oxygen to the roots." That, however, is not the only thing to be considered in respect to aeration. Frequently the roots get down too deep for air to reach them sufficiently, and they never ripen. Ripening is as necessary for the roots as it is for the branches; in fact, one is dependent to a great extent on the other.

Another reason for encouraging roots to remain within a reasonable distance from the surface is that the friendly bacteria, which modern science has taught us form so important a factor in plant life, are not found at any great depth below the surface, and without the assistance of these a soil is infertile. One may apply artificial nitrogenous manures, such as sulphate of ammonia, etc., by the ton and get no return. Happily, the desirable members of the bacteria family occur in all fermenting material, especially in farmyard manure, and it is impossible for healthy plant life to exist without something to be continually decomposing.

We read of the pioneers in uncultivated districts having good crops for a time till the humus left by the decay of the original vegetation is exhausted and then moving to "fresh fields and pastures new." The deserted land in time becomes the home of herds of cattle and then fertility returns.

I should like to think that the days of deep and wide borders are over, especially the deep

ones. It used to be thought that abundance of muck and plenty of heat were the principal necessities for indoor Vines and, to go a step further back, that a few carcasses of worn-out horses were desirable. It is now known that even an excessive dose of manure is absolute poison, but still some of us have not gone far enough from these old creeds.

In "Warrington's Chemistry of the Farm" we read: "The proportion of plant food present in soils is very small, even when the soil is extremely fertile, the bulk of the soil serving chiefly as a support and as a sponge to hold water." Then why should we go to the trouble of making a large and expensive border when a smaller one would be better? The smaller one is more under control, and if we only supply the necessary plant food at the right time we are very likely to obtain good results.

It is surprising what can be done even in 12in. pots. It is true the plants are generally exhausted with the first crop, but the crop itself is a killing one, and if it were not so heavy and the rooting medium was doubled the first crop might not be the last one.

I have charge of a small house in a villa garden where I planted four Hamburg Vines sixteen or eighteen years ago. The border is only 18ins. wide and about the same depth. It is raised above the ground level and so arranged that the roots cannot travel beyond the allotted space. No fire-heat has been applied for several years, yet these Vines continue to produce fruit which commands the highest price in the market. The berries are not as large as I should like, but they are perfect in every other way, and were there a chance to double the root space I believe they would soon be good enough to satisfy me. That means that the berries must be 1½ins. in diameter as well as having all the other good qualities.

Well, then, for the amateur who has only a small greenhouse and desires to grow a few Grapes and to have the border inside the house, I would recommend such border to be not more than 4ft. in width and against the front wall. This border should be supported with masonry 2ft. in height to form the boundary between the border and the walk. The rest of the house can be fitted with staging for plants which do not require a higher minimum temperature than 45° during winter.

It will be admissible to have a few odd specimen plants on the border, but on no account should it be so crowded that neither air nor light can penetrate. The border need only be made about 18ins. in depth at first, thus allowing for frequent top-dressing. Though it will kill most plants to bury their stems, the Vine does not mind it if it is done gradually, for it will emit roots from any part when covered with soil.

It may be said that it is better for the amateur to have the roots of his Vines outside the house, but there is such a temptation to grow early Lettuce, etc., on the prepared border and the jobbing gardener's spade has no conscience. I have known many promising Vines ruined by it.

WM. TAYLOR.

The Foam Flowers.—The most familiar of the little group of plants included in the genus *Tiarella* is *T. cordifolia*, one of the prettiest and most useful of plants for rock garden, edging, or woodland carpeting. The fluffy spires in white and pink of this charming thing, which rise from the trailing masses of delicate green leaves, are among the happiest of spring flowers. Moreover, *T. cordifolia* is hardly less attractive throughout autumn, when its crisp foliage assumes soft shades

of rose and ruddy bronze. This is one of the easiest of plants to establish, but it likes best a cool woodland loam or rocky bank about which its runners can root themselves. *T. unifoliata*, like the above, is a native of North America, but it is a species that is still uncommon. It differs from *T. cordifolia* in its greater size and instead of increasing by runners it forms a large clump like a *Heuchera* or *Tellina*. The leaves of *T. unifoliata* are 3ins. or 4ins. across, bronzy green, and the plant appears to be only partially herbaceous in many districts. In late spring it produces imposing spires of blossom some 18ins. or more in height and of a soft, creamy white set off with red-brown anthers. This species should have a cool, rather rich, moist soil with partial shade. It makes a good border plant where conditions are favourable, and it is, of course, quite hardy. There is at least one variety of *T. unifoliata* offered by nurserymen with more rosy flowers than the type, but *T. purpurea* appears to be a form of *cordifolia* with bronzy leaves and redder blossoms. *T. polyphylla* is a rare species from Northern India. It has not the reputation for hardiness and ease of culture which belongs to the foregoing, but it is so uncommon that little seems to be known of it.

The Madeira Orchid.—There are many hardy terrestrial Orchids for which room might well be found in numerous gardens where they are quite unrepresented. Our own islands yield us some charming plants of this kind, and where they are happy, as most of them will be in a moist situation, they are remarkably distinct and beautiful. For the lower parts of the rock or bog garden they are excellent, and those who possess such conveniences for their flowers will be well advised to introduce a few of these hardy Orchids among their treasured possessions. We do not purpose, however, at the present time to discuss these attractive plants in detail, but desire to bring before readers an exotic species which has proved hardy in the greater part of the United Kingdom and which is very beautiful. This is *Orchis foliosa*, which comes to us from Madeira, and bears the popular name of the Madeira Orchid. It resembles to a considerable degree our native *O. maculata* in its flower, but not in the foliage. The latter is broad and handsome, and the plant produces grand spikes of large flowers of a darker purple than the more typical forms of *O. maculata*. These create a most pleasing effect when in established clumps. It differs in height, according to its situation and the amount of moisture, varying from 1ft. to nearly 2ft. tall. It likes a good loamy soil with plenty of moisture, and when in a good position is very fine indeed. In some places it thrives with extraordinary freedom and vigour. A garden is known to us in Renfrewshire where this plant grows superbly and increases quite rapidly. In this garden there are hundreds of plants which make a grand sight in their season—summer and autumn. Roots may be procured and planted in spring.

Answers to Correspondents

TREES AND SHRUBS.

GROWING CYCLAMENS UNDER TREES (R. R.).—All, with the exception of *Cyclamen persicum* and varieties, may be grown in the open in warm borders and sheltered positions in woods. The planting should take place in October. The bed should be well drained and equal parts of fibrous loam, peat and leaf-soil used; to a naturally sandy soil add leaf-soil also a small quantity of rotted dung. Leaf-soil or coconut fibre should be used as a protection against ordinary frosts, and brackenfronds, etc., as a protection for the flowers against late ones. In ideal soil and situation the corms may be left undisturbed for several years. Use a wineglassful of Condy's Fluid to a gallon of water against the ants in the rose-bed. Sulfur and borax powders, sprinkled on the soil, also drive ants away.

Come and help mother!

THE little ones delight to play at helping Mother, and when the invitation is extended to Vimmy he is always ready and eager to help mother in the housework. He lightens every cleaning task, and cheerfully undertakes the work of brightening the house from roof to cellar.

There never has been a "help" like Vim—so reliable, so energetic and efficient. Upstairs and downstairs, all over the house it cleans and polishes everything quickly and easily—the drudgery of the work literally vanishes before the magic of Vim. Let Vim be your help.

Vim is splendid for cleaning Kitchen Tables, plain and painted woodwork; for scrubbing Floors, Oilcloth and Linoleum. Vim also quickly cleans Pots and Pans, Cutlery and Crockery, Earthenware, Glassware and Porcelain, Baths and Brass Taps. Don't apply Vim dry.

NEW SPRAYING MACHINES LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete without a Sprayer, in fact a Sprayer is absolutely essential to obtain best results.

During the War we supplied a considerable number of our well known Four Oaks Knapsack Sprayers—Rubber Diaphragm type—to the Government, and we have just re-purchased a small quantity back again, which have never been used. They are

made of copper but painted Service grey colour. They have various special additions to the ordinary machines, and the price to-day would be £5 each. We guarantee them to be in perfect working order as new. We will send one machine carefully packed, carriage paid, on receipt of 50/-, but cash must accompany all orders. We would supply 2 machines for 90/-, carriage paid.

Please mention this Paper when ordering.

MASSED ROSES.

The old plan of one bed many varieties has now been largely displaced by the far more effective method of one variety in each bed.

We cannot too highly recommend Golden Emblem for this purpose, the dark foliage making an admirable foil to the large golden yellow flowers.

The Price is 22 6 per dozen

[DECEMBER 22, 1923.]

THE WHITLOW GRASSES

BELONGING to the Crucifer family, the genus *Draba* consists of over 150 species, spread in their natural habitats over the whole of the North Temperate and Arctic regions, while many, too, are found on the Andes of Peru and Chili, and still others occur in New Zealand and Australia. The majority are minute alpine plants, forming neat rosettes of soft or bristly foliage and bearing white or yellow, rarely pink or purple, flowers. Among early-flowering plants the members of this genus must always occupy an important position. In addition to the brilliant golden yellow colour of the flowers of many species, the plants are characterised by a dwarf compact habit of growth. Each plant is composed of a mass of tufted rosettes, forming wide cushions which are very attractive all the year round. Though in many cases the flowers are small, still, in a mass and contrasted with the dark green leaves, they are very effective. They are ideal plants for the rock garden, planted on sunny ledges, or in the crevices between the larger stones, and are excellent wall plants, such species as *D. aizoides* soon forming a large cushion, which in spring will be covered with its yellow flowers. Easy of culture in well drained soil of a gritty nature, several species are useful for display in the alpine house. They may be grown in pans half filled with crocks, and in a compost of loam, grit and leaf-soil. During the time when not in flower the pans may be plunged outside in ashes, being only taken into the alpine house when in bloom.

The perennials may be propagated by means of division, or they are easily raised from seeds sown in a

little heat in March. Cuttings also strike readily in summer if inserted in sandy soil in a close frame. The annual kinds, which are of a more weedy nature, may be raised from seed sown outside in the open border. Of the numerous members of the genus the following is a good selection:

D. ACAULIS.—A choice little plant found growing in the crevices of rocks of the alpine region of the Taurus mountains in Cilicia. It forms tufts of hoary rosettes, just above which the yellow flowers with very short stems are produced in May.

D. AIZOIDES.—A common plant on the European Alps, this is one of the best for general purposes. Its tufts are composed of lanceolate-linear, ciliated leaves, while the comparatively large yellow flowers are borne in March on stems about 2 ins. high. The typical plant is found on limestone rocks, but var. *Zablbruckneri* grows on the highest granitic rocks of Carinthia and Styria. A stronger-growing plant is var. *Bertoloni*, from Northern Italy.

D. AIZOON.—A taller, coarser-growing plant than the former, with smaller flowers in April, also yellow in colour. It is only found on the mountains of Western Europe. After flowering, the stems develop and reach a height of 4 ins. to 5 ins.

D. ATHOA.—Closely allied to the above, with larger yellow flowers and very hairy seed-pods, this species comes from the Greek mountains.

D. AUREA.—This belongs to the looser-growing, less compact members of the genus, reaching a height of 9 ins., with leafy stems and yellow flowers in May. It is a native of the Rocky Mountains of Colorado and is usually found growing on moist banks.

D. BRUNIEFOLIA.—A loosely tufted plant forming broad cushions of light green foliage composed of narrow ciliated leaves. The large yellow flowers are produced in short racemes on stems about 3 ins. high in June. A native of the Caucasus, it is an old garden plant, having been in cultivation about a hundred years.

D. CAPPADOCICA.—From the high alpine regions of Cappadocia, this is one of the gems of the genus. It is of very tufted growth, with small rosettes of tomentose leaves and yellow flowers of good size on stems about 1 in. in height. It flowers in May.

D. DEDEANA (syn. *D. aizoides* var. *Dedeana*) is a close-cutted little plant of cushion habit from the Pyrenees in Northern Spain, with dark green hairy leaves. The flowers are white and very freely produced in April on stems under 2 ins. high. It delights in the gritty soil of the moraine, with full exposure to the sunshine and plenty of water while growing.

D. FLATA.—This Himalayan plant is one of the tallest in the genus, with leafy

THE YELLOW-FLOWERED DRABA AIZOON.

D. grandiflora (L.) Boiss. (syn. *Androsace grandiflora*)—In Mex. and Central America to the Mexican border.

D. galienii (H.) Boiss.—The general aspect of *M. grandiflora* with pinnate and dentate leaves, with *D. grandiflora*, this species forms a new group, distinguished by their soft foliage, late or late or purplish flowers and long style, resembling exclusively the *Andros* of South America. *D. galienii* grows about 6 ins. high with racemes of pale lilac flowers in April. Like those of *D. incana* the seed pods are twisted.

D. GRANDIFLORA.—A very free-flowering tufted plant with tomentose foliage and racemes of white flowers in April and May on stems 4 ins. high. It is a native of the Andes of Ecuador and Peru, and is found growing in the crevices of rocks on Mount Chimborazo at an elevation of 14,000 ft. It has proved quite hardy, succeeding well in a sunny position in gravelly soil, and is quite a dainty little plant with a profusion of white flowers. It is worthy of a place in the choice part of the rock garden.

D. IMBRICATA.—There are two plants grown under this name in gardens. The true plant comes from the Caucasus, with very small rosettes of linear leaves, flower-stems 1 in. high bearing only two or three yellow flowers in a short raceme or head. The commoner plant usually seen under this name is *D. rigida* from Asia Minor, with wiry stems 2 ins. or plus, long carrying heads of many rich yellow flowers.

D. INCANA is a somewhat weedy species with small white flowers. Worth growing, however, is a variety with yellow flowers known as var. *Adamsii*.

D. LENSELTERIANA.—A neat little plant from Corsica with dark green foliage in dense cushions and large yellow flowers on very short stalks in April. It makes a good pot plant for the alpine house.

D. MAYRI.—An excellent rock plant, forming low, densely tufted, bright green patches somewhat in the way of *D. Dedeanii*, but the white flowers are not so large and are produced in closer heads. This is also a native of Northern Spain, and probably only a form of *D. Dedeanii*.

D. PYRENAICA (syn. *Petrocallis pyrenaica*).—This is one of the choicest genus for the select part of the rock garden, where it should be associated with rock plants of the smallest type. Though the name implies that its home is in the Pyrenees, it is by no means confined to that region, but is also found in Switzerland, where it is grown at an altitude of 7,000 ft. to 10,000 ft., mostly on abruptly sloping calcareous rocks. In our gardens it succeeds best in the moraine, but may also be established in rocky crevices. It makes a tuft 6 ins. or more across in the form of a cushion, with rosettes of minute leaves that are divided into three or more narrow lobes. From the centre of each rosette springs a cluster of from four to six delicate pale lilac flowers of good size, which are produced from May to the end of June. It requires to be taken up and divided when the tufts begin to show signs of going bad in the centre.

D. rigida is an early-flowering, charming little species from Asia Minor often grown under the name of *D. imbricata*. Its slender stems, with yellow flowers, are very freely produced in early spring. It is easily grown on a sunny ledge in gritty soil, and soon makes large tufts of bright green foliage.

D. roemeriana.—This charming little plant is widely spread over the European Alps from the Pyrenees to the Carpathian Mountains. It has white foliage in a soft tuft, with heads of large white flowers on stalks about 1 in. in height. It is best grown in a rocky crevice so that moisture does not remain on the foliage in winter, but it also succeeds in a moraine. It is, too, a good pot plant for the alpine house, as grown under

DRABA RIGIDA IN A ROCK CREVICE.

DRABA RIGIDA; GENERALLY GROWN AS *D. IMBRICATA*.

THE DAINY LILAC-FLOWERED DRABA (PETROCALLIS) PYRENAICA.

glass, the white leaves retain their freshness better than when exposed to bad weather outside. *D. t. var. frigida* is a form with less hairy leaves and smaller white flowers.

There are many other species grown in gardens

closely resembling some of the above, but they are somewhat difficult to distinguish from each other except in the fruiting stage. Other white kinds are *D. Salomonii* and *D. Sundermannii*, both easily grown plants. W. L.

stately in bearing and beautiful in both flower and foliage. There are also varieties in soft shades of blue which are distinctly good. All of these possess the virtue of permanency, and the white one, at least, can generally be relied upon to come true from seed. Another excellent Columbine for growing singly or in groups in almost any soil under trees is *A. formosa*, which has foliage of a peculiarly attractive and gentle green and pretty little flowers in scarlet and orange daintily poised at the ends of the many-branched thin stems.

Dicentra formosa is a useful old plant for carpeting a considerable space with its dove-coloured, fern-like foliage, and this it will o'ertop, with unfailing regularity every summer, with its drooping heads of rosy purple blooms. *D. formosa* appears to thrive on neglect, tree-drip and sunlessness, and the rather larger and rosier *D. eximia* is hardly less easy to please. Many of the Hellebores can be grown to perfection in shade that is not too heavy, and a page might be written of their splendid qualities both as flowering and foliage plants, but they are all greedy feeders,

HARDY PLANTS FOR SHADY PLACES

THOUGH often abandoned to carpeting shrubs—when not to despair—there are not many sunless places, even beneath the drip of trees, for which a variety of suitable flowering plants might not be selected. Ferns and dwarf evergreens always have their charm, and it is suggested that shady spots given up to these are of necessity either wasted or neglected. My point is that, with or without these, there are flowering perennials which will give brightness and colour and a wider and more diverse interest to such ground, and that without going beyond the sphere of the easier and less expensive kinds.

One word, however, to the uninitiated in this matter! It has to be borne in mind that the soil under trees is often very impoverished and solidified. Not many plants will prosper in such a medium without a certain amount of preparation, but the extent to which this has to be carried must be decided by the particular requirements of each set of plants selected—and also, of course, by the nature and state of the ground. To give one familiar example, one may plant *Omphalodes verna* in a cool and kindly, free vegetable-mould and every little scrap will soon ramp away. Try the same thing, however, in the tough and stubborn and naked earth that lies beneath, say, an Evergreen Oak, and it will probably refuse to have anything to do with such a heart-breaking prospect. Yet even such uncompromising "stuff" as this can be rendered fertile and more genial by a little loosening, and by working in at the same time a dressing of rough leaf-mould, old farmyard manure or decayed vegetable rubbish. Indeed, a blend of all three of these may be considered a first-rate standard dressing for the bulk of shade-loving plants, and one that may be used in the soil and as a mulch.

Troublesome as it may often be in other parts of the garden, there is much to be said on behalf of the Welsh Poppy (*Meconopsis cambrica*) as a plant for associating with Ferns and other shade-loving things. This is a true perennial, a hearty grower practically anywhere and an all-season bloomer. Its pale green foliage and lemon yellow flowers are really very delightful—prejudice omitted—and the orange buff form (not the double) is even more charming. The latter is not nearly so rampant a trespasser as the type, and it comes true from seed, by which means both sorts are most satisfactorily established.

The Yellow American Poppy, once called *Meconopsis petiolata* and now known as *Stylophorum diphyllum*, bears a cousinly resemblance to the Welshman, but it is a good deal more like a much enlarged Greater Celandine (*Chelidonium majus*). This is a handsome shade plant for a cool, moist place, making a branching growth of 18ins. and bearing deeply lobed, silky leaves in a fresh green and numerous large golden yellow flowers. Few plants can be more pleasing grouped in among Ferns than this, and it does not stray like *M. cambrica*, nor yet like that other beautiful weed *Eomecon chionantha*. But admirable as the last-mentioned Chinese Poppywort undoubtedly is, it is not always a reliable bloomer in sunless places. Even so, it is well worth a place if only for the sake of its beautiful bluish

grey cyclamen-like leaves and the few big white flowers that it occasionally affords. Root restriction, plenty of moisture in spring and a good baking in the later summer are what this probably wants to induce it to flower more freely.

With the same white, saucer-shaped flowers, four-petalled and centred with golden stamens, and much the same leafage, is the allied *Sanguinaria canadensis*. This, however, is not nearly so vigorous a plant as the foregoing, but it is hardy enough and will generally do well when established in shade that is not too dense, the soil being moist and freely drained. Though *S. canadensis* does

MOST USEFUL OF WOOD LILIES, THE SHADE-LOVING TRILLIUM GRANDIFLORUM.

creep after the manner of *Eomecon*, we find that it is much more liable to perish, our wet winters being too much for it. Still, the plants will often survive for several seasons, and in many gardens they are as long-lived as most things.

The Trilliums must always be numbered among the choicest of shade plants, but for them an average soil needs more than a surface "tickling." They love the deep vegetable loam, spongy with humus, of moist wood bottoms, and for such spots there can be nothing more desirable. There are several species and varieties, *T. grandiflorum* and *californicum*, the latter with various forms, being perhaps the best known. Unfortunately, slugs have such a partiality for the Wood Lilies that their culture on anything like the scale they so richly deserve is often rendered disappointing.

Under deciduous trees there are few more pleasing perennials than *Aquilegia vulgaris* in its best forms. The large-flowered, tall-growing white, sometimes listed as "Munstead White," or *A. v. nivea grandiflora*, is wonderfully effective, being

and those who aspire to do great things with Hellebores must not be afraid of pick and shovel and be prepared for ravenous demands upon the manure and compost heap.

Foxgloves one need hardly mention, the white form being especially lovely in sunless spots. *Digitalis ambigua*, a perennial with several spikes, short and erect, strung with bells in nankeen yellow, also well deserves the hospitality of any woodland garden. Scarcely less stately and suitable is *Campanula grandis* (latifolia), of which the violet-blue assumes almost an azure tint in light shade, and the milky white columns of the variety *alba* are equally charming. *C. persicifolia* in some of its more robust forms can also be relied upon to do with very little sun, and no less may be said of *C. urticæfolia* (*Trachelium*) and *C. latifolia*, which gives us so many superb varieties for woodland planting.

Many other Bell-flowers will come to mind as desirable for our purpose here. We must, however, pass on to the Loosetrites, to the tall, creamy

white-spaced *Lysimachia clethroides* and *L.L. Henryi* and *Nemophila*, the last with its golden-rayed form. One of the most delightful shade groups I have ever seen consisted of *L. clethroides*, *Funkia scabellii* and *F. Fortunei*, the creeping *Looselia* alluded to, some clumps of *Ivy-leaved Cyclamens*, *Anemone trifolia* and a few mossy rocks. We have managed also to make a success of grouping *Gentiana asclepiadea* in several forms with the elegant tufts of *Blechnum Spicant*, *Vinca difformis* and *Hemerocallis flava*—these in cool soil under tall deciduous trees with *Erythroniums*, little Welsh *Daffodils* and other bulbous plants for earlier days.

The *Euphorbias* cannot escape mention when discussing shade plants, and of the varied choice the genus provides, one can only mention *Cyparissias*, *polychroma* and *pilosa* as being among the most generally useful. *Tiarella cordifolia* is indispensable, and the much taller and statelier *T. unifoliata*, which does not put out runners, but remains in a single massive clump, is admirable for "lifting" any level, sunless spot occupied by lowlier plants. *Saxifraga Geum*, *cuneifolia* and *umbrosa*, including their innumerable varieties, are always the right thing in the right place in shady or half shady woodland, and *S. granulata* is delightful in such conditions.

Omphalodes verna has been mentioned, but it will not do to omit the larger and lovelier *O. cappadocica*, which, with us, is equally easy, and *O. nitida*, all true and happy woodlanders in any fairly cool ground. *Anchusa myosotidiflora* can also justly claim admission with the rest and best of the Borageworts. Nor can one pass by what is perhaps the pick of the basket when ease of culture is considered in addition to colour and grace, viz., *Borago laxiflora*. Taller and coarser, but not to be despised in the wilder parts of one's garden are the common Borages and *Anchusa sempervirens* (*Alkanet*), both of which will do with practically no sun.

Several of the *Fumitories* are excellent plants for the purpose under discussion, the pretty *Corydalis lutea* being perhaps the most redundant and most generally useful. Among the early-flowering kinds is *C. cava* (of the lists) with ferny, blue-grey foliage and purple flowers, but the white form is even more lovely, looking like a Roman Hyacinth and smelling nearly as sweet. Perfume is a rare attribute in this race, and *C. c. alba* will prosper in the densest shade. Closely allied to the above are two or three other species, among which *C. solida* is conspicuous for its larger size. Then there are *CC. ophiocarpa* and *cheilanthesifolia*, both succeeding in shady well drained places where their tender grace is not rudely imposed upon by more robust neighbours.

There are some really choice things among the *Pulmonarias*, which are perfectly content without sun. The genus *Aconitum* (*Monkshood*) affords a selection of great diversity for early and late blooming, and there are among the *Doronicums* a number of kinds which will flourish with a minimum of direct sunlight. The *Tradescantias*, especially *T. virginiana* and its beautiful varieties, might also be much more widely used in moist, shady places. One has, in addition to all these, but to mention the easier *Primulas*, *Lily of the Valley*, *Lamiums*, *Epimediums*, *Wood Sorrels* (*Oxalis*), *Claytonias*, *Forget-me-nots* and *Linarias* to indicate what an extensive choice one has in flowering shade plants of the simplest culture and lowest cost. J.

[This question of shade-loving plants is a very important one, but gardeners seem often needlessly disheartened. Given a little attention for one season, there are few places where *Hypericum calycinum*, for instance, will not establish itself.—F.D.]

THE WITCH HAZELS

THE Witch Hazels (*Hamamelis*) form an interesting and very distinct genus of small trees or shrubs, natives of North America and Eastern Asia. Four species and two varieties are in cultivation, two species from America, and two species and two varieties from Asia.

The resemblance of the leaf of *Hamamelis* to that of our Common Hazel Nut and its supposed magic properties as a divining rod are apparently responsible for the popular name of Witch Hazel,

which was first given to the American species *Hamamelis virginiana*.

Seeds, which ripen in most seasons, are the first method of increase we may consider. They are erratic in germinating, frequently taking from eighteen months to two years. We hear of pots of seeds being discarded as useless by the owners before the close of the first year and perhaps this is not surprising. If a few seeds are sown each year, however, and seedlings do not appear within six months, the pots should be plunged to the rim

MOST POPULAR OF WITCH HAZELS, HAMAMELIS MOLLIS.

ATTAINS THE STATURE OF A SMALL TREE, HAMAMELIS JAPONICA VAR. ARBorea.

outside. Assuming that this is done there will probably be a dozen or so pots, representing the harvests of two or three seasons. From these it should always be possible to find seedlings appearing in sufficient quantity to increase the stock of plants, and in the case of *H. virginiana* plenty of seeds should be sown if increase by grafting is intended, this being the stock mostly used to work the Asiatic species upon.

Layering is a ready means of increase, the natural spreading habit of the branches lending itself to their pegging down without difficulty. Here, again, the length of time the layers take to root, usually two years, confronts the grower, but by pegging down branches every year, if needed, there is always a supply of rooted layers to draw upon.

Grafting about April is also practised, using *H. virginiana* as a stock, the beautiful Chinese Witch Hazel, *H. mollis* being the species most extensively propagated by this method. The stocks should be established in pots, 5in. is a useful size, so that the grafting may be done under glass. Place the stocks in the propagating house two or three weeks before they are required to have the sap well on the move before placing on the scions.

The Hamamelis from Asia thrive best in a well drained loamy soil of a light, rather than a heavy nature. When planting young bushes work in plenty of leaf-mould, or a little peat. The American *H. virginiana* appears to thrive in most soils, some of the best I have noted being on the borderland of a wood, with moist conditions. Some care is necessary in the transplanting of specimens of any size. October, or, preferably, after flowering at the end of March or early in April, is the best time for the work, taking care that a fair amount of soil adheres to the roots.

When selecting positions for planting, two things in particular should be borne in mind; the first that, as the Witch Hazel flowers during the roughest part of the year, protection is desirable, and the second that, as they flower in advance of the leaves, association with, and a background of evergreens, is an advantage. The most effective planting at Kew is about a dozen specimens of *H. mollis* in a collection of large and small *Buxus* (Box). There is no question of the hardiness of the Hamamelis for British gardens, but because of the flowering season, it is not uncommon to find them planted against a wall for shelter and with very good results, a south-west or west wall being, perhaps, the best.

H. japonica.—Though known as the Japanese Witch Hazel, this species is a native of China and Japan. At first a spreading shrub, it eventually grows into a large, irregularly branched bush, though with a little training, beginning early with a leader, the species makes quite a pretty small tree. The thin, narrow yellow petals are produced during January and February. The variety *arborea*, as the name suggests, is stronger in growth than the type, with the tendency to form a small deciduous tree. It is usual to find the flowers of var. *arborea* opening before *H. japonica*, and they are a shade or two darker (more golden) in colour. In the other direction we have the pretty pale lemon blossoms of the variety *Zuccariniana*. As only a proportion of the seedlings produce pale flowers it is necessary to propagate by grafting or layering to be quite sure of obtaining the right plant, unless, indeed, it is possible to wait until the seedlings flower. In nurseries, forms with rather highly coloured calyx-lobes are variously named var. *rosea* and var. *rubra*, but as plants with this characteristic appear among batches of seedlings, varietal names scarcely seem worth while.

H. mollis, the Chinese Witch Hazel is the most showy and valuable of the genus. It has larger narrow ribbon-like petals, golden yellow in colour and deliciously fragrant. The flowering season is from December to January, and though frosts, if severe, may dim the flowers, the effect is only temporarily eclipsed, and after a warm day or two the blossoms appear as bright as ever. When the bushes get large enough, this is a glorious shrub to cut in mid-winter, using in vases with it the red-tinted foliage of the Mahonia, Berberis Aquifolium. In summer the hazel-like stems and leaves give *H. mollis* quite a distinct, ornamental character. Though first introduced from China as, apparently, a form of *H. japonica*, over forty years ago by Maries, and grown in the Coombe Wood Nursery, it was only during a visit of the late Mr. George Nicholson, twenty years later, that its distinct characters were recognised and identified.

H. vernalis.—This is the most recent of the Witch Hazels to be introduced to our gardens. Professor Sargent sending the first plant to Kew in 1910. Chief interest attaches to the shrub because the flowering season is January and February, whereas the other American species, *H. virginiana* opens from September to November. As a flowering shrub for our gardens it is not the equal of the Asiatic species. As *H. vernalis* spreads by means of suckers these may provide useful stocks on which to graft *H. mollis* and others.

H. virginiana.—The Virginian Witch Hazel is the oldest inhabitant of the family in our gardens, its first introduction being as long ago as 1736. A native of Eastern North America, writers in that country describe it as one of the best known and

most common of woodland shrubs or small trees. The yellow blossoms open first in September, just when the leaves begin to turn yellow and orange, and still more flowers open after the leaves

THE RED-CALYXED FORM OF HAMAMELIS JAPONICA.

have fallen, lasting usually through November, or even later. Though not a bush or small tree exactly deserving of a prominent position among flowering shrubs, the Virginian Witch Hazel may worthily find a place in the shrubbery border. Its requirements are not exacting, while to the lover of interesting plants *H. virginiana* possesses attractions in flower and fruit.

Kew.

A. O.

ALPINES FROM THE PASS OF MONT CENIS

(Concluded from page 649.)

TRACKING upwards, the banks were covered over a considerable area with masses of *Rhododendron ferrugineum*, the so-called "Alpen Rose" of the mountains or "mountaineers." Being in full bloom, its ruby red flowers produced a very picturesque effect. Continuing on above the level of these was the distinct *Ranunculus rutafolius*, one of the rarer members of this family, with its grey fanlike foliage and white flowers rather disappointing when compared with some of the other alpine members of this group. Higher still, was quite a considerable quantity of the more desirable and prettier in every way *Anemone baldensis* with its characteristic larger white flowers and much more graceful foliage. This

is quite one of the best for the alpine garden, if made happy. Plants were becoming interesting now, and neutralised, in a way, the discomforts of the weather, which kept "weeping" intermittently and was quite cold at the higher level we were attaining. High up, the track was over a considerable stretch of short grassy turf, among which were still lingering the dainty flowers of the Vernal Anemone, *Anemone vernalis*, one of the first of the flowers to unfold on the melting of the snow. It was also fairly plentifully sprinkled with "Edelweiss," although the position was not the usually dangerous one traditionally associated with this universally known alpine. The pretty dwarf *Lychnis alpina* also peeped up out of the turf in this area. Still pushing up

without any view or indication of a lake to encourage us, we were up among the snow, with some beautiful alpine buntings as company, and almost on the point of returning when a magnificent plant of the King of the Alps, *Eritrichium nanum*, with its delicate silvery grey downy cushion and incomparable blue flowers pecked up at us right in the pathway, like a rare jewel in a setting of stones. This acted as a tonic and, hunting round in the immediate neighbourhood, quite a quantity of *Eritrichium* was seen, but none to surpass the plant first noted. Hereabouts we had quite a glorious, if short, time. The very local *Primula pedemontana* with its rusty-edged rosette was in full flower in among the cracks and crannies in the rocks, quite a lovely colour picture in places.

Saxifraga retusa, another high local plant, dwarfer than *S. oppositifolia*, which had been seen (along with *Dryas octopetala*) on the way up, was here, with dark green hard cushions covered with its deep claret-coloured flowers, which usually do not occur below the 7,000ft. level. Other interesting high *Saxifragas* noted were *S. aspera* and *S. biflora*, the latter in very wet places along with the pretty annual *S. stellaris*, a plant well known in the alpine districts of our own country.

We visited the same ground two days later in much better weather conditions, but with the same military hindrances (or necessities) preventing an early start being made; however, a quick journey resulted in the desired "Lago Fresco" being reached on this occasion. On the boulders by the lake, *Eritrichium nanum* was fairly plentiful, with its always delightful brilliant blue flowers, probably in the same position as seen by a more distinguished visitor some years ago.

Thlaspi rotundifolium was a beautiful and welcome find: usually, isolated plants with rounded heads of rose pink flowers peeping up, for the most part, out of the somewhat barren screes. A welcome surprise was the finding of one or two good white-flowered plants. This species had also been seen the previous day among the stony wastes leading up to Lac Clair.

Among the *Androsaces*, the loveliest of all this beautiful family was *A. glacialis* with its green cushions covered with deep rose-petalled, compact flowers—probably, after *Eritrichium*, the finest jewel of the higher Alps and, like it, very difficult, if not impossible, to grow and bloom satisfactorily away from its habitats high up at the edge of the snow; also the hard grey-leaved *Androsace helvetica*, very pretty with its pure white, stemless flowers. This I have flowered well on the moraine, after complete protection from the damp, moist atmosphere during the winter.

Lloydia serotina (the rare Snowdon alpine) was locally plentiful and a few late flowers of the dainty *Soldanella alpina*. The Glacier Ranunculus, *R. glacialis*, was in flower, but not in abundance, also sparingly in the lake basin, and the bright blue flowers of one of the *Gentians*, possibly *G. imbricata*. On the homeward journey a diversion was made to see *Apulegia alpina*, which was somewhat past its best, but still very beautiful in the wooded parts at the south side of the lake. I am afraid the blue of the flowers did not come up to expectation. One had been led to expect a pure sky blue flower in place of the somewhat purplish blue flowers. I had seen a lovely display of this Alpine Columbine quite equal to the above both in size and colour at the York Show in the middle of June.

Fortunately, the day set apart for searching out the lovely little Lac Clair up in the mountains

at the back of the hotel did not clash with the military, who still were busy on the opposite side of the lake. The day was fine and the walking pleasant until the rough stony screes were reached, of which a considerable stretch had to be traversed before one suddenly looked down on the exquisite "Lake Clair." The grassy slopes in the early part of the route were, in places, very beautiful with the creeping shrubby-leaved *Veronica Allioni* with its pretty erect, clear blue flower-spikes. *Douglasia Vitaliana* was noticed, but was out of flower, as was also *Petrocallis pyrenaica*. Both, however, were in flower at a higher level, the latter being particularly fine. It is quite one of our best "moraine" plants and usually flowers well.

The dwarf large-flowered *Campanula Allionii* was abundant in places in the dry, stony bed of the stream. Among the blue flowers which varied a little in shade was a rather nice pink-flowered variety, but only a single plant. Higher up the stream more on the bank sides, the sweet and dainty *Viola cenisia* pecked out at one, its pretty purplish blue, yellow eyed, round-petalled flowers beautiful indeed, standing out from its strong background, plentiful, but only, so far as seen, in a very limited area, and the flowers did not seem to vary much, only a rather pretty pale blue variety being noticed. What a rush the higher alpine have: flowers one day in the brilliant sun and forming seeds the next, which are ripened in a very short space of time. Although the *Viola cenisia* flowers could only have been in bloom a short while, quite a quantity of ripe seed was obtained. Still moving upward, *Campanula cenisia* was just peeping up from under the stony screes with its roots well down in the grit sodden with the continuous melting snow from the steep slopes above. Odd plants had been seen in flower, but it was full early for this *Campanula*, which is usually at its best in the month of August. Higher still, in the same stony waste, *Thlaspi rotundifolium* with its rosy pink flower balls obliterating the leaves was in evidence, and it was interesting to see what a distance the "stocky" roots had travelled down into the ever-moistened grit under the larger stones that overlaid them. About the only other plant among this stone field, where plants were few and far between, was *Saxifraga biflora*, with foliage somewhat like the "Club Mosses" and not very striking flowers.

On the moraine, thrown up between two torrent beds, vegetation was much more evident, and included quite a good sprinkling of the lovely blue flowers of *Gentiana bavarica* or more possibly, its higher form, *G. imbricata*, seeing that the altitude was very much greater than down at the Mont Cenis Lake, where the true *G. bavarica* was fairly plentiful. *Anemone baldensis* was also here in plenty, and near by flowering plants of *Geum reptans* with its pretty yellow blossoms and divided leaves, and lower down its fluffy seed-heads, along with those of *Geum montanum*. The "screes" stage of the journey was long and rather tedious, and no indication of the long-anticipated lake was vouchsafed to us, but we pushed on to a ridge in front with the hope of finding the long-looked for lake over the "top," and were at last rewarded for our efforts by finding the charming blue "Lake Clair" in a basin below, with high snow-capped mountains and small glaciers towering above it.

After resting, admiring the lake and its enchanting surroundings and also lightening our load (lunching), we found that by the sides of the lake the lovely high form of *Gentiana verna*, known as *G. brachyphylla*, was fairly plentiful, with its lovely blue, almost stemless flowers peeping up out of the stony bed, and we

were fortunate in finding two pure white-flowered plants of the same *Gentian*. *Veronica apylla* had lovely deep blue flowers of good size and harder foliage at the higher levels, but was not nearly so attractive at the lower, the leaves being looser and fleshier and flowers as a rule much smaller; the result, in the garden, of plants raised from seed some three years ago being similar to the last and not worth troubling with. Among rare English alpine, the very dwarf creeping *Azalea procumbens* was plentiful, carpeting the ground and in full flower (including some with white blossoms), which it rarely is in our gardens, where, even if established, it either flowers very sparsely or not at all. *Arenaria sedoides*, which is one of the Ben Lawer's alpine, grow in green compact mats with very small white flowers, not particularly interesting as a garden plant. The parasitic *Bartsia alpina*, a plant familiar in its North of England habitat, was seen from the Mont Cenis Lake up to the little lakes at the higher altitudes, very often associated with the *Gentians* in boggy places. *Erigeron alpina*, another Scotch species, was frequently seen, as was also the lovely white-flowered alpine Butterwort.

Saxifraga diapensioides was seen in flower on the last day of my visit to Mont Cenis, a short day, as tracks had to be made early in the afternoon for Susa. The plant, as usual, was in the "occupied zone," so the early part of the morning was spent in collecting seeds of *Viola calcarata* and other plants of interest that happened to be in the vicinity of the nearest sentries. Operations ceased about eleven o'clock, when a dash was made for the locality, all likely rocks being examined *en route*, and after about an hour's walk it was found fairly plentifully in the crevices and at the foot of some large boulders, hard, grey-green cushions tight on the rock flourishing best, right on the underside away from sun for the greater part of the day and sheltered from direct rain. Plants more exposed were not nearly so happy, and in some instances were clean burnt up. On a hurried journey back a diversion was made to see *Cortusa Matthioli*, a pretty primula-like plant which I had not seen previously in its native haunts, although it had been happy in the garden for many years, being received as *P. luteola*, an altogether different plant.

The hotel people became very independent towards the week-end, and evidently wanted to be rid of *en pension* visitors, owing to an expected rush of motor enthusiasts! (to put it mildly), for some motor speed trials that were to take place on the Sunday from Susa up the Italian side of the pass to Mont Cenis—what a desecration to such a place and such surroundings! Two visitors who stayed on, managed, for a long day—the military being otherwise occupied for once—to get clear away, and so effectively that it meant staying out the night as well, they having got astray in the mountains adjacent to the Little Mont Cenis, and eventually found themselves at Susa next morning.

As the place was beginning to "buzz" with motorists, and they are not "silent" in these parts, I did not altogether regret having to leave, and motored down by the Hospice, now for the most part transformed from its former peaceful and more suitable purpose into a busy, dirty and untidy barracks. The early part of the pass is very steep, the drop being very considerable in a very short distance, traversed by short zigzags and known owing to its steepness as "The Staircase." The journey opened out beautiful views, but motoring is too rapid, especially when down-hill, to be of any use for close observation. The quaint city of Susa was eventually reached in good time for my train on to "The Maritimes."

Middlesbrough.

T. ASHTON LOFTHOUSE.

THE LAST SHOW OF THE YEAR

A DISTINCT end-of-the-season air pervaded the Royal Horticultural Society's Hall at Vincent Square, Westminster, on December 11, when the Society met for the last time this year. The attendance was small and the exhibits were of a conglomerate nature. Orchids, Carnations and Chrysanthemums were the principal flowers on view, and these were supported by hardy shrubs. Fruit was represented by a small but splendid collection of Apples from Messrs. G. Bunyard and Co., and the remainder of the exhibits were of sundries, paintings and preserves.

The Orchids included another collection of the splendid *Cypripedium* seedlings raised by Mr. G. F. Moore. These are noteworthy for their

was displayed by the several vases of Sir Mackay Edgar, Red Ensign, Reginald Cory and Lady Inverforth as shown by Messrs. Stuart Low and Co., who also had nice flowering plants of *Erica melanthera* and *Acacia platyptera*. Donald, a new perpetual-flowering Carnation, is a good bright crimson, and it is said to be very free-flowering. It was shown by Mr. C. Engelmann, who also had a valuable set of white varieties.

Although Messrs. Keith Luxford and Co. included a number of gigantic Japanese Chrysanthemums in their exhibit, it was the Pompons of the tiniest possible size that attracted most attention. In two very large vases of graceful sprays of the miniature type were Julia Lagrave of warm crimson-maroon colouring, Yellow Snowdrop and the white Mary Pickford, no larger than a sixpenny piece, and the attractive amaranth Frances Hutchinson.

The preference for the smaller, graceful type of Chrysanthemum was continued with the collection of sprays from seedling plants raised this year by Messrs. Sutton and Sons. These were practically all Singles, and while there was none worthy of a first-class certificate, all the many sprays were quite good and just the right thing for ordinary decoration. For those who do not care for the bother of keeping stock plants over the winter and of striking cuttings in the spring, the raising of seedling plants each year has much to recommend it. It should always be recognised, however, that the great majority of the plants so raised will only produce quite single flowers, and that there will be few doubles among them, though nearly all will be highly decorative.

Chrysanthemum Golden Butterfly, which was excellently shown by Messrs. Scott and Wickham, is a greatly improved W. H. Lincoln and bears good fully double flowers on long, stout stems.

A novel type of the miniature garden was introduced by Mr. S. Smith, who brought a number planted with little Cacti of many different sorts. Mr. Fred G. Wood had many similar receptacles planted with alpine.

Among the shrubs was a large number of dwarf conifers suitable for the rock garden. These, and several *Skimmias* and *Berberis dulcis nana*, were staged by the Orpington Nurseries Company; while Messrs. L. R. Russell, Limited, had standards of *Euonymus* and Lavender and various Ivies.

Another collection of dried flowers and Grasses was brought from the French Intensive Gardens, and many of the species were very attractive.

The garden sundries included Mr. J. Haw's patent watering pots, a new pattern pruner by

Mr. C. Jardine, garden ornaments in stone by Messrs. Sanders and Co., the Hardy rustless steel spades and Radium and Cross Bone fertilisers, and Major Walker's fruit tree protector.

Paintings of gardens and floral studies were freely shown by the same artists as a fortnight ago, and Mr. Percy Cane contributed excellent photographs of gardens carried out to his design.

NEW AND RARE PLANTS.

Chrysanthemum Brightness.—A pretty little late-flowering Japanese variety after the style of Winter Cheer, but brighter and shaggier. It appears to be dwarf and bears plenty of sprays of neat, bright rosy mauve flowers. Award of merit. Shewn by Mr. H. W. Thorpe.

Cypripedium Chrysostom Chardwar variety.—This is a gross flower of somewhat floppy habit and not equal in merit to the similar varieties shown a fortnight ago. It may be described as being a gigantic *C. insigne* with a broader band of white and some crimson flushing on the standard. First-class certificate. Shewn by Mr. G. F. Moore.

C. Gwen Hannen Chardwar variety.—Briefly, this is an immense *C. insigne* of excellent type and form. First-class certificate. Shewn by Mr. G. F. Moore.

C. Prince Albert Chardwar variety.—A very distinct long-stemmed rounded bloom with uncommon rich purple colouring on the standard. First-class certificate. Shewn by Mr. G. F. Moore.

C. Warrior var. H. Green.—A large, rounded *C. insigne* variety of excellent type. Award of merit. Shewn by Messrs. Armstrong and Brown.

Sophro Lælio-Cattleya Eileen.—The rich glowing colours of the blooms rendered this the most attractive of the new Orchids. The sepals and petals were a deep rose pink and the lip was a bright velvety crimson. Award of merit. Shewn by Messrs. Stuart Low and Co.

GAULTHERIA SHALLON

OF the small group which comprises the genus *Gaultheria* this shrub is the largest, easiest and most common. It was introduced by Douglas nearly two hundred years ago from North-West America, and the many references made to it in the Journal of the celebrated botanist and traveller testify to the warm regard in which he held the species. *G. Shallon* makes a dense evergreen bush, or thicket, of erect reddish stems which may be anything from 1 ft. to 4 ft. or even more in height, and amply furnished with ovate, almost heart-shaped, leathery leaves of a rich green and as large as those of an average Apple tree. Once established (it often takes some time to settle down) it grows rapidly and spreads by means of suckers, an attribute that may be highly desirable in the right place but is somewhat troublesome in another. As a flowering shrub *G. Shallon* is the most worthy of its race, the bloom racemes, which are produced at the terminal leaf axils in early summer, being some 2 ins. to 3 ins. long and bearing many nearly globular flowers of good size in a pale silvery pink. The deep purple berries are luscious and of good flavour. While almost any soil, save that which is very dry, will suit *G. Shallon*, the best specimens are usually seen in deep, cool loam or alluvial deposits, in well drained peat or the damp, leafy mould beneath woodland trees, especially pines. When planting, it is desirable to put in clumps rather than separate roots.

THE NEW LATE SPRAY CHRYSANTHEMUM BRIGHTNESS.

great size and uncommon colouring. Messrs. Flory and Black and Mr. Harry Dixon also shewed small collections of very good *Cypripediums*. Messrs. Sander and Co. had a general collection which included some beautiful *Brasso-Cattleyas*, *Cymbidiums*, *Lælias* and *Odontoglossums*.

Among the general flowers the several displays of Carnations were particularly bright. The vivid colouring of a large vase of Edward Allwood alongside the rich shade of Wivelsfield Claret in the collection of Messrs. Allwood Brothers was very striking. Topsy and the deliciously fragrant Mrs. C. F. Raphael were on the same stand. At one end a collection of *Dianthus Allwoodii* illustrated the long flowering season this useful type enjoys. Rich carnation colour

CENTIPEDES, MILLIPEDES & WOODLICE

THERE is a sufficient likeness between the active centipede and his more sluggish relative, the millipede, to make it somewhat difficult for a novice to distinguish rapidly between them. The dilemma is often solved by killing both on sight, which is something of a mistake.

Whatever the verdict may be regarding the function in life of the millipede, it is generally conceded, by those conversant with his ways, that the centipede is not a vegetarian, but feeds largely on earthworms and probably clears off large numbers of such insects, etc., as frequent his subterranean burrows and lairs, under flower-pots, bricks, etc. Unlike most of the millipedes the centipede is flattened in shape and takes a good deal of exercise.

The tropical centipedes are very poisonous and many even of our English species have poison glands attached to their first pair of legs, by means of which they have been seen to kill earthworms and bluebottles. The centipedes most frequently seen in gardens are two. One is *Geophilus*, which is long and thin with from 30 to 200 segments, most of which have a pair of legs attached to them. This genus is of a yellowish colour, slightly tinged with brown, has no eyes and some of its species give a phosphorescent light like the glow-worm. The other common genus is *Lithobius*, which is shorter than *Geophilus* and more strongly made, of a chestnut colour and an appearance of having been well polished with furniture wax.

There is no need to disturb either of these creatures, for they are probably doing a useful work in destroying noxious insects and though unattractive are too small to annoy mankind.

Both centipedes and millipedes belong to the order Myriapoda, which we may roughly translate as "Many-legs," a most appropriate name; as is that of centipede or hundred-legs for *Geophilus*. Forty is the approximate number of the walking appendages of *Lithobius*. A local name for these among Arabs is "Forty-four-legs," while in the Eastern Counties of England they are familiarly called "Forty-legs."

To distinguish between a centipede and a millipede observe closely the segments into which each is divided. The centipede has one pair of legs on each segment, while the millipede has two pairs, which are thin and, in the aggregate, look like a fringe of hairs. The millipede is of a snake or worm-like appearance, with a practice of coiling like a watch spring when touched, but otherwise moving but slowly; whereas the centipede is alert and, when long, has a habit of arranging itself in a complicated kind of figure of eight, withdrawing rapidly from the light into the earth or beneath a sheltering stone.

The millipede is less nearly allied to the insects than the centipede, and is generally sluggish in its movements. Its sole defence appears to be a power of exuding an offensive odour from glands near its tail. The body is usually round like an attenuated slate pencil. Its eggs are laid from May to July in a nest of earth the size of a small nut, made by the female. At first, the young have but three pairs of legs, but new ones are grown and appear in groups from time to time, probably after each moult.

Of English millipedes there is one genus, *Polydesmus*, the members of which have flattened bodies; these have but nineteen segments, are protected by bristles and may be found congregated together in considerable numbers. They are not likely to be confused with the centipedes, which are more active and have an air of knowing their

way about much more than any species of millipede.

Much damage is done to Potato roots and Strawberries by the millipede known as *Julus*. That roots and fruit are eaten by them is certain, and though some persons declare that other creatures

Nos. 1 and 2, Centipedes (*Lithobius* and *Geophilus* respectively). No. 3, (a and b) a Millipede, *Julus pulchellus*. No. 5, a typical Woodlouse. No. 6, Small red Woodlouse, *Trichoniscus roseus*.

must make the first hole, those who have suffered largely from their depredations find it hard to believe that the *Julus* tribe do not act on their own initiative. One small species of *Julus* often shares the name of wireworm with the larva of the click beetle; under the microscope, it may be seen to be decorated along each side with a row of crimson spots.

No. 4. Another destructive species of Millipede, *Julus pusillus*.

The Pill millipedes, of another genus, roll themselves up much like the Pill woodlice, but do not form a ball, are in fact more like a thick wheel with a depression where the axle should be.

The woodlouse is widely spread and fairly omnivorous, but though it may dispose of some noxious creatures of small size, it is not a safe companion for delicate plants. It is a small, oval crustacean (a relative of the crab and lobster tribe) and one genus is called *Armadillo*, from the defensive armour plating with which its back is covered. The size varies greatly as it continues its growth after maturity. Some of the smaller species are very prettily coloured in shades of red and pink, as well as grey and yellow.

The woodlouse is a careful mother, carrying her eggs in a brood-pouch under her body until they hatch. This creature, like the millipede and centipede, is found in damp places, under boards, flower boxes, etc., and if undisturbed becomes sufficiently numerous to make its presence felt.

In order to check the increase of millipedes and woodlice, some good may be done by hollowing out large roots, such as Potatoes, Mangolds, etc., and placing them in marked spots beneath the surface of the soil, whence they should be frequently removed, cleared and replaced.

Leaf-mould is often a resort of these little pests, so that on obtaining a fresh supply it is a wise precaution, unless it is wanted for lime-hating plants, to work slacked lime into it. Long manure is also a source of trouble and if turned and pecked over by chickens several times, is likely to be safer.

If land is found to be infested by these pests a dressing of gas lime may be useful, or ordinary quick lime or super-phosphate of lime may be used. The Ministry of Agriculture also advise one or two ounces of powdered naphthaline to each square yard of land, which should afterwards be watered. Soot, or soot and water is also recommended, or proprietary insecticides may be applied as directed. The removal of decaying roots and frequent turning over of the land will disturb intruders and lay them more open to the attacks of birds. In greenhouses and pits crumbling mortar should not be tolerated; properly pointed walls afford no harbourage.

B. M. L.

TRENCHING AND DIGGING

WITHOUT a thorough preparation of the soil no crop can be grown satisfactorily. Yet how often one sees plants and seeds put into the ground after a very inadequate digging and working of the soil. Plants in a shallow-tilled soil grow to all appearance very well up to a certain stage and month, but when a dry spell of weather comes, the roots, being near the surface and having exhausted the nutriment of the soil there, and being unable to penetrate downwards through the hard pan of soil below, fail to finish the crop properly, whether of fruit, flowers or vegetables.

There is no better time than the late autumn and early winter for digging and trenching work.

I am not directing attention merely to the open plots in the vegetable garden, but to the soil preparation in every department. If, for instance, shrubs are planted in hard, unbroken soil, one easily sees the dire results a few years afterwards. They do not withstand dry weather in ordinary seasons and often collapse altogether in exceptionally dry ones. If it is not possible to trench the whole of the new shrubbery border, the soil for several feet round should be trenched for each specimen at planting-time, and on the first opportunity the remaining ground should be similarly treated. The shrubs and trees will then grow freely and prove a pleasure to the owner. The new herbaceous border and those renovated must, of course, be trenched over the whole of the space the plants occupy. Many of the kinds so grown will never prove satisfactory unless the soil is trenched; surface mulching will not supply the deficiency. Roses thrive in deeply trenched ground, even in cases where the soil is stony and poor. I well remember a case in point. The cultivator had purchased a new residence; the ground was stony, almost peaty in places, poor indeed, and its position was high and, naturally, overdrained. It was freely predicted that Roses could not be grown satisfactorily in it, but as a result of trenching and judicious surface-mulching very fine blooms were grown of

high enough merit to win silver cups in good competition.

Of course, it is unquestioned that the trenching of the soil for vegetables is really necessary if high-class produce is to be obtained.

The actual treatment of the soil must vary according to its character. It would be unwise to bring up gravelly loam to the surface unless the cultivator had an unlimited supply of well rotted manure to put in as the work proceeded. To meet the average case such gravelly subsoil should be well loosened but left below. Some small portion of the good top soil would fall and mix with the poor subsoil; this could not be prevented, nor is it desirable that it should be, as by this means

a greater total depth of rich loam will gradually result. In the case of a clayey subsoil I am all in favour of bringing up a portion of it at every trenching and leaving the lumps on the surface exposed to the weather all through the winter to become pulverised and sweetened. Finally, a word as to the treatment of the best, the top, spit of soil. If it is grass ground, I would peel off the turf thinly, stack and use it judiciously afterwards, and when sufficiently rotted, for the benefit of the choicest crops. In all cases the immediate underlayer would be buried only a few inches to help on its disintegration, as I find that there is never any difficulty in getting some of it mixed with the lower layers. GEO. GARNER.

CORRESPONDENCE

CLEMATISES ON THEIR OWN ROOTS.

IN reply to Mr. W. Gater, Sheffield: These can be had by means of striking cuttings. There are two methods, using either inter-nodal cuttings or young shoots in spring stripped off from the node. I have had good success with both, the kinds being *Clematis montana* and *C. tangutica*. In the Island we can strike them in the open, in loose, porous compost, shading them from the sun until the roots are formed, and constantly watering them overhead. Spent house ashes (a good deal of wood ash in them), on well forked-up ordinary garden soil gave excellent results, but leaf-mould and sand or peat moss and sand should be quite satisfactory. According to the late Sir Isaac Bayley Balfour's formula, my cuttings are just stuck into the loose soil, without firming in any way.—"WESTERN WIGHT."

I READ with interest the note by H. Gater, Sheffield, on the above (December 8, page 640). I have been trying for several years to establish plants, purchasing these from various growers and bestowing great care on the soil, shading of roots, stems, etc., but always with the same result, viz., a total collapse after varying periods. Two years ago, however, motoring through Newton Abbott (Devon), I stopped at a nursery owned by Messrs. Fuller to purchase certain plants and saw there some healthy-looking plants of *Clematis* standing 3ft. to 5ft. high. I spoke to the genial old foreman about my trouble with *Clematis* and he suggested my trying some of his plants, which he stated were "grafted in the old-fashioned way." I tried five of them—Jackmanni and J. alba, Nellie Moser, Miss Bateman and Lord Neville. Sure enough these plants have done excellently. They have all bloomed (except Miss Bateman, of course), this year, since June last and were full of flower up till the wintry conditions (which, by the way, were

exceptionally severe for this part of the country), of a fortnight ago. I think I paid 2s. each for these plants and I know he had a couple of dozen plants of various sorts when I made a call at the

THE VERY DISTINCT ACACIA VERTICILLATA.

nursery in October last. I may add that these plants were put in along a trellised arch and get very little protection from sun. They get pulled about badly by gales, to which we have been subjected almost continuously this year. With the milder conditions now being experienced it looks as if Nellie Moser will succeed in opening several large promising buds.—H. R. STERRETT, Exeter.

THE FIFTY BEST ALPINES.

MAY I tender thanks to all contributors for their interesting and helpful lists. It is noticed that some appear to favour *Convolvuli*—especially *C. Cneorum*, but owing to the evil

reputation of the race (especially on chalky soil), I have not yet attempted any of the kinds. Can *C. Cneorum* be trusted not to strangle everything? I would suggest that *Verbena chamaedryoides* is not sufficiently hardy, and that *Raoulia australis* produces very uninteresting flowers, though the foliage is certainly beautiful.—PURLEY.

ACACIA VERTICILLATA.

IT is but a small proportion of us who are so fortunately placed that we can plant this lovely Wattle in the open air and allow it to grow 8ft. and 10ft., even 12ft. high. Yet there are places in the West of England where this can be done, and is done, and it is a useful fact to remember when we are considering large plants suitable for furnishing a large, cool house.

The photograph which I send should serve to convey an excellent idea of the general appearance of the plant with its thin woody stems, dark green conifer-like foliage and full, fluffy little heads of pale greenish-yellow flowers, exactly the tint of the rind of a ripe lemon. There is, however, one extra charm which the camera cannot portray for us and that is the subtle, but delicious perfume which these flowers give out. If one looks closely at the illustration, one sees that not only are the expanded heads notable for their abundance, but the number of unexpanded buds is correspondingly large and this means an extended flowering season. Now, let us picture such a shrub as that, of the proportions described, and, remembering that the flowers begin to expand in February and continue until the end of April, we can quite appreciate that *A. verticillata* is a plant of real value.

In common with the rest of its family, the plant appreciates a soil in which sandy peat largely predominates, although it will grow splendidly in a mixture of peat and turfy loam kept evenly moist. When planting, take care to make the soil very firm all round the fibrous roots and see that they never suffer from lack of water, especially during the early stages. Some indication as to their requirements in the direction of temperature may be gleaned from the fact of their growing outdoors in favoured localities, and all that is necessary is to keep them as cool as possible, just excluding hard frosts. The habit is so densely branching that one need not fear to cut freely, once the plants have attained a fair size. Indeed, cutting rather does good than otherwise—if carefully done—for in removing the branches needed for decoration, one admits light and air to the centre of the plant and so encourages the production of young and vigorous growths. Those who happen to possess those mild and sheltered gardens where frost rarely comes—and does but little injury when it does—should by all means try the plant in the open, for it forms a splendid garden shrub very early in the year when the spring sun is gathering power and the misty cloud of golden fluffy heads is almost hiding the foliage from view by its abundance.—H. W. CANNING-WRIGHT.

ABOUT FREESIAS.

THE raiser and grower of coloured *Freesias* no longer ploughs a lonely furrow. Every year his confrères increase in number, which means more people take a first-hand interest in all that concerns them. May I, then, put some of my recent experiences before readers? (1) Contrary to expectations, as I imagined we were not having much of a summer for ripening purposes, there are practically no duds among all my thousands of corms. My impression is that there was not as much sunshine as we usually have, but that we had a fair amount of warmth; at any rate, I was able to sit out of doors in an evening pretty

often, which is not always the case. (3) Has any one tried my suggestion of heating the corns before planting them, except my one correspondent, who lately wrote to tell me he had done so, with the most beneficial results—"the ones that I put in heat are especially strong"? With me this year heated and non-heated are much of a muchness. (4) This year there is a distinct difference in vigour between the white and next-door-to white seedling and the yellows, pinks and mauves. The first-named, including many of which the large ivory-white Primrose Day is the seed parent, do not look so robust. This is rather a reversal of my experience. (4) A big surprise packet came to hand in September. A letter from a lady in the Isle of Wight accompanied by a few seed pods of Freesia seed ripened in the open in her garden there. The seed was sown on September 6, but so far (December 7) only one seed has germinated. In this lady's garden Freesias have been grown in a dry, warm position out of doors for some years. I am trying some of her hardened bulbs, which she was kind enough to send, in the open here, with just an inch of coarse fibre over them. I fancy British saved seed from plants grown in the open garden is very uncommon. Does any one know of any other instances?—JOSEPH JACOB.

TO COLLECTORS OF ENCRUSTED SAXIFRAGES.

I AM making a collection of Encrusted Saxifrages and am anxious to get into communication with other growers and collectors. I have already nearly 300 different kinds.—C. KIRCH, 52, *Albemarle Road, Beckenham, Kent.*

GLADIOLI IN VICTORIA.

IN THE GARDEN of August 18 (recently received), on page 430, there occurs a mis-statement—doubtless owing to a printer's error—in my notes on Gladioli in Victoria, the approximate latitude of Geelong being given as 30° S., instead of 38° S. I would be obliged if you would correct this error, as it renders several of my remarks as to climate, etc., most misleading. The climate at Geelong (38° S.) is temperate, while at 30° S. (which is close to the border between New South Wales and Queensland, and many hundred miles further north) it is rather more than sub-tropical.—"AUSTRAL."

SMALL-FLOWERED CHRYSANTHEMUMS.

THE Editor's footnote, page 628, issue December 1, in which reference is made to the small-flowered varieties for border decoration, brings back to my mind the days, a generation ago, when there were about twenty varieties grown generally for cut flowers in the open border during the late autumn and early winter months. I grew such as far north as Lancashire, and in Hampshire. The plants were grown on the west side of walls in groups in such a way that a rough framework could be readily erected to bear mats and tiffany rolled up during the day and in mild weather, and placed over the plants in frosty weather. These plants provided quantities of flowers for cutting and room decoration. The idea was to have masses of blossom in distinct colours in deep vases, and these old varieties provided them at a minimum cost and without taking up valuable space under glass. There was no disbudding, so that each spray formed a bouquet in itself. The chief care was to keep the flowers dry. In Hampshire in open winters I have cut as late as the second week in January. Generally, I found we had some blossoms spoiled one year in eight. In the North the plants were secured to high walls by strands of wire, and protection was readily afforded. Chrysanthemum Snowdrop and about half

a dozen other sorts of the Pompon family were also grown in large pots for use at Christmas. I am sure we should be doing the right thing to grow more of such small-flowered sorts in these days.—G. G.

YELLOW ROSES.

IN the note upon "Some of the New Roses of 1922," Mr. H. L. Wettern states that the best yellow of the year is undoubtedly Mable Morse. I cannot endorse that statement: W. E. Wallace has been finer in Scotland. In his description of Mable Morse Mr. Wettern writes that "Although we had regarded Golden Emblem as perfection so far as yellow Roses are concerned, this new Rose is even better, and should prove the crowning point, unless, of course, the raisers have something better coming along." We had several hundred plants of Mable Morse in flower this season here, and although it is unwise to condemn a Rose when one has only had experience of it for one season, I am convinced that it will never oust or rival Golden Emblem. That variety, from every standpoint, is the supreme yellow Rose that is at present in commerce. It is not, I should hope, the last word in yellows, but it is one that will be extremely difficult to beat. It is a masterpiece and a credit to its raiser.

Mable Morse is described by its raisers as "The finest yellow Rose the world has yet seen." The same raiser describes Florence L. Izzard as "The queen of all yellow Roses." It is, of course, a later edition in yellows and was sent out in 1923. I venture to express the opinion that Golden Emblem will never be displaced by either. I repeat again, that it is a masterpiece.—GEORGE M. TAYLOR, *Edinburgh.*

THE POMEROY APPLES

STEPPING into a fruit market last week I came across a couple of hampers of the Old Pomeroi Apple, and although not taking in appearance, the flavour was such as must be pronounced "good." In a few Herefordshire orchards I have come across three varieties called Pomeroi, viz., Lancashire Pomeroi, the Old Pomeroi or Pomeroi of Somerset, and the Pomeroi of Herefordshire (syn. Kirke's Fame, Peach, Sussex Peach and Russet Pine). Pomeroi's name is a corruption of Pomme du Roi (the King's Apple). Old Pomeroi is of medium size, conical and obtusely angular, skin greenish yellow, covered with thin, grey russet, with patches of russet and red on the side next the sun, strewn all over with numerous large, dark russet dots. The stalk is short, inserted in a round, russet cavity, the flesh firm, yellow, crisp and highly flavoured, and the fruit in season until January. Pomeroi of Herefordshire is an early, richly flavoured dessert Apple, in use during October. The fruit is a nice dessert size, in coloration similar to the russet varieties, with a few broken streaks of crimson next the sun. The flesh is yellowish, tender and juicy, sweet and of a delicious flavour. Pomeroi of Lancashire is a rather soft-fleshed culinary Apple and in season about the same time

as Lord Suffield. The flesh is white and it is a good cooker. GEO. LOVELOCK.

THE RIDDLE OF THE ROSE.

FIFTY years ago John Hutton Balfour, Professor of Botany in Edinburgh, quoted to his class the Latin "Riddle of the Rose."

"Quinque sumus fratres, unus barbatus et alter imberbisque duo, sum semiberbis ego."

The riddle is of great antiquity, and the following fine translation of it has been made by Professor F. M. Caird.

"Five brothers take their stand
Born to the same command;
Two darkly bearded trown,
Two without beards are known,
And one sustains with equal pride
His sad appendage on one side."

The above was found in "A Student's Life in Edinburgh in the 'Seventies," by "Alisma."

HAS GOLDEN EMBLEM BEEN SUPERSEDED?

In the Wild Rose the five sepals remain attached to the hip and will invariably be found—two bearded on both sides, one with a beard on one side only, and the remaining two without beards.—H. W. L.

THE TRITELEIA.

TRITELEIA UNIFLORA is a singularly pretty flower when grown in a mass; a single plant growing alone fails to give us a true impression of the charm of a spreading group of this flower with its narrow leaves and milk white or bluish flowers open to the sun. It comes from warmer parts, hailing, indeed, from the Argentine, but is hardy in many parts of the United Kingdom, suffering more, I think, from winter wet than from cold. It should have ample drainage, and nowhere have I seen it finer or more flourishing than in the gravel path of a garden in the suburbs of Edinburgh, where the original plants in a border near by had seeded and produced a host

of seedlings which in turn bore seeds and gave rise to many hundreds of plants, which when in full bloom made a most fascinating sight. Yet there are gardens much further south where *T. uniflora* does not flourish for any length of time. It grows from 4ins. to 6ins. high and flowers in summer, and should always have a sunny place, so that the flowers may remain open as long as possible. Bulbs are cheap and may be planted 3ins. deep in autumn. Free, open, well drained soil is best.—S. ARNOTT.

GARDEN NOTES FROM NICE

THE much-desired rains have at length visited this coast, and a week or ten days without a sunny day has caused many a grumble from the new-comers who do not realise how much they were needed. As it is they have come too late for those who love their autumn gardens. December, however, has its special charm, for there are so many fragrant flowering shrubs that scent the air on these brilliant and still days that follow on the late autumn days of rain.

Buddleia auriculata is now replaced by *Chimonanthus fragrans*. It is difficult to say which is the sweeter, but it is quite certain that the fragrance of the *Buddleia* travels much farther than that of the *Chimonanthus*. *Freylinia cecidoides* is also of most penetrating perfume, while its beautiful kinsman *Cestrum aurantiacum* is as scentless as an *Abutilon*. *Lavandula dentata* and the flowering *Rosemarys* are also particularly noticeable on a December morning. Sweet-leaved *Geraniums* are in full growth and scent the air as you pass; but I must own that the flowers of *Iris stylosa* (or *ungicularis*?) do not seem to me to have an appreciable scent this coast.

That delightful little evergreen shrub *Phyllica capensis* deserves more attention than it gets. The French name for it is "*Bruyère du Cap*," which rather explains its charm while very misleading as to its name. It is not a Heath, as they would suggest, but a *Groundsel*, and its rich green heath-like shoots are crowned by a tightly congested head of white flowerlets that defy winter rains and storms—neat and tight and white spite of everything for two or even three months! In a smoky atmosphere the whiteness would not last so long, I fear, but in country air it should be worth a trial in southern counties, as it is hardier than the sweet *Buddleia auriculata*, which blooms at the same time and gained an award the other day. Its apparent and only defect is that it is straggly in habit, and after many years of struggling with it I, in despair, took a pair of shears and clipped the whole bank on which it had grown for so long. This was done in May, when it had already made many long green shoots, and to my surprise when I next saw it, in the month of October, I found a neat carpet of green heather-like shoots already tipped by the white specks that develop by and by into the neat button-like heads of bloom. It makes a capital contrast to *Lithospermum rosmarinifolium*, which I shall this year subject to the same drastic treatment in the hope it may succeed as well as the first; but the *Lithospermum* is not naturally a straggler in the same way. All the same, it needs keeping in order on occasion, and so these two evergreen shrubs become a necessity to winter gardens on this coast. In the matter of soil *Phyllica capensis* seems omnivorous, and it is equally at home in sun or shade

when its tendency to straggle is kept in order. I hope some day our Kew friends will report on its hardiness, as they have done with the *Buddleia*. It deserves a place in any garden where neat shrubs are used for edging or grouping.

Clematis balcanica is another good plant blooming at this season that should not be forgotten either on this coast or in more northern gardens. Its dainty purple-flecked bells, so creamy and attractive as they hang in pairs on the slender climbing stems, are speedily followed by silvery shining heads of feathery seeds that are almost as attractive as the flowers, and the finely cut and dentate foliage is at its best at this season, but to keep it at its best it also needs cutting back severely in February or March. *Clematis Armandi*, however, is far the most beautiful of the winter

or early spring flowering section, and should be planted in some suitable place where it will not suffer severely from drought. In some gardens it refuses to grow freely, but I feel convinced that with good soil and plenty of water it is a climber that everyone should grow; unfortunately, French nurserymen rarely catalogue it, so that it is little planted.

Acacia podalyriaefolia is the most showy of all shrubs or small trees and perhaps the most lovely of all the "*Mimosas*," as they are termed by the French. The hot dry season has suited it to perfection, and the length and abundance of the flowering shoots is amazing. If only its lovely sprays would live when cut and in water how faultless it would be in its beauty at full mid-winter.
E. H. W.

PROFITABLE INSTRUCTIONS for the MANURING, SOWING and PLANTING of KITCHEN GARDENS, 1599

A Pæan on Carrots.

THIS little book merits attention partly because of its rarity, but much more on account of the intrinsic interest of its contents, which give us a first-hand peep into a well-to-do citizen's garden of the year 1599. As I write I have this book by my side, and so I can state that it exists. Although the work was mentioned and the actual date (1599) given in Charles Bellingham's posthumous edition of Sir Hugh Platt's "*Garden of Eden*" in 1665, and although this same edition, as well as one in 1603, is mentioned by Lowndes in his "*Bibliographer's Manuel*," writers on gardening matters like Mrs. Evelyn Cecil seem very doubtful if a copy is still in existence. No mention of either edition is made by Weston in his *Catalogue of English Authors*. Johnson, who wrote the well known "*History of English Gardening*," can never have seen a copy or he would not have followed verbatim the reference to it in the "*Garden of Eden*" by just mentioning it as "*Gardener's Kitchen Garden*," thereby shewing he neither knew its correct title nor the author's name; you draw Pritzel blank.

Small wonder, then, that Mrs. Cecil's note in her bibliography is "no copy has been found," and that although she had never seen a copy of the second edition herself, she mentions that Hazlitt included it in his third "*Collection of Bibliographical Notes de visu*," as if he were rather a lucky man to have done so.

Naturally, something about the author will add interest to its contents. Positively, I think I am correct in saying, nothing is known about him, but if some very strong circumstantial evidence in Owen and Blakeway's "*History of Shrewsbury*" (1825) may be admitted as proof, then we do know something. A very cursory examination shews that the writer was a good man who had been shocked at the condition of his poor neighbours in a time of great scarcity and who wished to tell people how to grow garden produce—more especially Carrots—against such another visitation. He lived in Shrewsbury, and he was a practical gardener himself. Now for the circumstantial evidence that seems to prove that the Richard Gardner who is mentioned in Owen and Blakeway is the same man as the author of "*Profitable Instructions*."

(1) In the *History* the Richard Gardner who is described there (Vol. I, page 348) as a "dyer

and free of the Drapers' Company" is a man who has the town's welfare at heart. He lived "on the Severn bank near Bagley bridge," and thinking it would be a good thing for his neighbours if he could find coal in the vicinity, he set to work and "he found by his great diligence and travell greate store of sea cole" in 1571 in Emsterie Haye. For this he is praised.

(2) About the year 1595 the seasons were very unpropitious in England, and, in addition, many parts were visited by the plague. Shrewsbury felt the pinch badly, so much so that certain of the Aldermen and others were deputed in 1596 to go to London to try to buy foreign corn, which appears to have been imported from "Danskke (sic), Denmark" and other places. They succeeded in purchasing 3,200 bushels, which were sent round by sea to "Bristow" (Bristol), now inseparably connected by gardeners with English Frises and the "Flower of Bristow." The price of wheat in 1597 was 18s. a bushel, whereas in September, 1598, it fell to 4s. 4d.

(3) When in 1628 Heralds visited the town, they entered with others the pedigree of the Gardners. This looks as if the family had lately got on in the world and is in harmony with the beneficent spirit in which "*Profitable Instructions*" is written.

(4) A laudatory poem, as was customary at that period, appears after the Introduction by one Edward Thornes. On page 416 of Vol. I in Owen and Blakeway another Thornes is mentioned who signed a declaration of loyalty to the King in 1642. From this it is probable that the Thornes were a family of some consequence and, if so, the poem adds to the prestige of Richard Gardner and makes it more probable still that the writer of the book and the highly respected citizen are one and the same person.

(5) All that has been put forward is only circumstantial evidence, but I cannot help feeling that although it does not actually prove that the Richard Gardner who is mentioned in history and the Richard Gardner who wrote this book are in reality one and the same person, yet the circumstantial evidence that I have brought forward makes it more than probable that "the dyer and draper" who is commended for his public spirit in searching for coal in 1571 is none other than the man of whom

Edward Thorne, Gent: wrote in his commendatory poem:

"The poore which late were like to pine,
And could not bue them bread
In greatest time of penurie,
Were by his labours fed.
And that in reasonable rate
When Corne and coine was scant
With Parsnip and with carret rootes
He did supplie their want."

Ending up by saying:

"We wish as he dooth well deserve
His welfare and his health,
That hath so greatly profited
Sallopian commonweath."

Let us now turn to the book itself and speak of its contents. They give us a first-hand idea of what went on in the well kept kitchen garden of a comfortably off citizen of the period. The copy before me, which might be catalogued as of immaculate condition with good wide margins, measures 7 3/16 ins. by 5 1/4 ins. and, including everything, consists of thirty-two pages. The title-page tells us that it is a book of "Profitable Instructions for the Manuring, Sowing and Planting of Kitchen Gardens, very profitable for the commonwealth and greatly for the helpe and comfort of poore people, Gathered by Richard Gardner of Shrewsburie," and that it was published in London by Edward Allde for Edward White in 1599. The first six pages are taken up by the Title, Introduction and Commendatory Poem, and the last one and a half by a religious exhortation to live well and a prayer which has all the simple grace and smooth diction of those which we find in the old Church of England Prayer Book, the making of which we have now to lament as one of the lost arts. Mr. Thorne's poem is rather sorry doggerel, but the Introduction by the author might have been written by St. Paul and "Englished" by the translators of our splendid Authorised Bible.

The old man knew he was growing old, but before his powers failed him he would tell his fellow townsmen of his gardening experiences. "Amongst all the practises, knowledges and experiences which ever I received from Gods mercies in temporall blessings, I doe undoubtedly perswade myself that my practise and experience in Garden stufte, or the good benefits therein, dooth best benefit, helpe and pleasure the generall number of people, better then any other practise that ever I tooke in hand in temporall causes whatsoever. And therefore good neighbours and friends of this my native soyle, accept of this my short and simple penning of this my practise and experience in Gardening causes herein mentioned."

The practical part of the work is methodically arranged. He begins at the beginning; that is, seed saving. We all know the necessity of good and reliable seed; and, to ensure this, how many save their own seed? Gardner was a firm believer in seed saving himself because he knew it was not well to trust all that was offered for sale. He gives up a whole page when writing about saving Onion seed to exposing the "greate and abominable falshoode of those sortes of people which sell Garden seedes." He does not mince matters, and goes on to say that as the sum total of their robberies, if added up, would be found to be more than that of "all other robbing thieves of this whole land" they are "more worthy in conscience to be executed."

Seed-saving was, in those days, of supreme importance, and so our author gives very minute instructions about how to select and grow the plants which are to be seed-bearers in the case of Carrots, Cabbages, Parsnips, Turnips, Lettuces,

Beans and Onions. Other kinds are mentioned, and he purposely omits "many other seedes of lesse accompt and so common in use," but which, all the same, he did not consider so generally useful. He gives the width of the beds (4 1/2 ft.), the distances the plants should be apart, the number of rows in a bed, and how they must be staked or tied up. For example, when Cabbage have grown a vard high "then beset the braunches with rises and gird the braunches and rises with a stringe of packe thread or such-like or els the weight of the braunches and the winde will breake them to the losse of the seedes." He also says "Take heede to them" when the seed is getting ripe and net them, for, unless this is done, "the birds called the Bull Finch will destroy them sodainly." We still used the word "rise" or rice locally, and go to the woods to get pea-rices. In the preparation of the beds he was a great believer in dung; "you must have a special care to mucke well your garden once in two yeares or else you shall lose more in the profit of the Garden, then the mucke is worthe by much." As a substitute, or in case mucke cannot be had, weeds should be put in a heap to rot. This is "very goode to rancken the garden in wante of other mucke."

The different ways of sowing seed is next considered in a general way. Four ways are enumerated, but "the only best way when the bed is made is to take a staffe of the greatness of a mans thombe, or somewhat greater, of a yarde and a halfe long and then strike a small Rigall or Gutter" in which the seeds are to be sown. Various seeds are then dealt with seratim, including, in addition to those already mentioned, Leeks, "Cowcumbers" and Radishes. A page, too, is given to Globe Artichokes.

Gardner, it is true, kept an eye on the moon when he was sowing his seeds, but I am quite sure

he had no use for such an almanack or such instructions as Stephen Gilbert appended to his *Florists' Vadenecum* eighty-two years afterwards, one of which reads "Sow or plant when the moon is in Taurus, Virgo and Scorpio and in good aspect of Saturn." Again, the old man knew the value of space. Edwin Beckett himself could not be more careful not to waste any ground. "At the end of May you may set Cabbadge plants in those places, where the carrets doe want and in want of Cabbadge plants you sowe good Turnip seedes or Radish seedes thereon and have a good profit."

Before his closing exhortations and prayer Gardner returns once more to his beloved "carrets." He recounts how from the produce of less than four acres of Carrots and 700 Cabbages "many hundreds of people were well refreshed thereby for the space of twentie daies when bread was wanting amongst the poor." Instructions are given how to keep and store Carrots, also how to use them in cookery; also at what prices the seeds and the roots should be sold, ending with a quite excusable puff of his own seeds and incidentally advising town people to plant all the Carrots they can if they think they are likely to be besieged; just in the same spirit, as we may remember, John Evelyn advocated Oaks, and our present-day rulers Wheat.

Richard Gardner's last wish is "that the people may have store (of Carrot seeds) of their owne growing for their gardens, which is my desire, if it may so please God." And so he ends the practical part of his small book. All that remains is his exhortation, farewell and concluding prayer.

It is a most absorbing and interesting work, and one could wish there were plenty to go round instead of the one which is about to be offered by Messrs. Wheldon and Wesley, being in all probability the only first edition in existence. J. J.

SOME GAGE PLUMS

TO those anticipating planting varieties of Plums the following sorts will be found to be of value on account of the quickness with which they come into bearing. By placing the trees over a slab of stone, slate or other similar material, fibrous roofing will be assisted, which helps greatly toward early bearing. A dusting of bone-meal, also a dressing of flowers of sulphur will assist the health of the tree. Both materials should be incorporated in the soil as planting proceeds.

DENNISTON'S SUPERB is a first-rate dessert Plum, ripening from the middle to the end of August. Of American origin, it has a first-class reputation. The fruit is above medium size, short, oval and slightly flattened. Skin pale yellowish green marked with a few purple thin blotches and dots and covered with a rich bloom. The flesh is yellow, firm, juicy, rich, sugary and vinous, and altogether this is a Clingstone of great merit.

EARLY GREEN GAGE (Reine Claud Hative).—The fruit is small and round, and the skin yellowish green with a red cheek on one side and strewn with dots. The flesh is yellow, tender, sugary, juicy and highly flavoured. This is a free-stone variety, ripening at the end of July.

EARLY TRANSPARENT GAGE.—An excellent early Plum raised by the late Mr. Rivers about 1866, this variety has come to stay. The fruit is medium roundish, apricot yellow with crimson spots, and delicious in flavour. It succeeds on all systems, but wall cultivation should have preference.

LATE TRANSPARENT GAGE.—Of more recent introduction than the above, being introduced

by Messrs. Rivers about 1892, this is a constant cropper. Fruit large oval, yellowish green, with a purple flush and luscious looking. This is a Gage of great merit, makes a good standard, and is excellent as a dwarf fan-trained tree inasmuch as the wood grows rather dwarf and spreading.

COMTE D'ALTHAN'S GAGE.—This variety takes rank as one of the very best of Gages, being, in fact, a glorified, coloured Green Gage of medium size and richly flavoured. The skin is bright reddish purple covered with a dense bloom and strewn with yellow dots. It is a free-cropping variety when associated with other varieties. It ripens about mid-September and was introduced about 1869. For culture in pots this Gage is first-rate, the flesh being a rich yellow, juicy and sugary, with a fine vinous flavour and separating freely from the stone.

BYRANSTONE GAGE is a late, large, similar old Green Gage, raised at Bryanstone Park and supposed to be self-fertile. This variety is worth attention, it being useful owing to its free-cropping propensities as a standard south of London. I have also seen good crops in the orchards of Herefordshire and Somersetshire. It is said to be the result of a cross between the old Green Gage and Coe's Golden Drop.

REINE CLAUDE DE BAVAY bears large, roundish, yellowish green fruit. The flesh is very juicy, sugary and firm; the stone comes freely away. The growth is moderate, and in its early stages soon becomes set with fruit-buds. Raised about 1843, it adapts itself to most forms of training. As a pot tree it is especially good. All the Gage varieties appreciate a sufficiency of lime in the soil. GEO. LOVELOCK.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Lettuce.—A sowing of a small Cabbage variety such as Tom Thumb may be made in boxes of light soil, and if placed in a warm greenhouse the seeds will soon germinate. When the young plants are through the soil, remove the boxes to a cooler house or pit and give them a light position close to the roof glass. As soon as the plants are large enough they may be pricked off into boxes or on a mild hot-bed.

Broad Beans.—Where these are well through the soil a little earth may be drawn around the plants for protection from frosts, and it will be a support for them during windy weather.

Jerusalem Artichokes.—These may be lifted and stored in a cool shed or placed in a heap outside under a north wall and then covered with ashes. Select a sufficient quantity of medium-sized tubers for planting later on, although such work may be carried out in the near future if the soil is not too wet. Plant in lines 3ft. apart, and a distance of 1ft. is necessary between the tubers, while they should be covered to a depth of about 6ins. To secure good roots an open situation should be chosen, and the soil deeply dug and liberally manured. When lifting Artichokes care should be taken to pick out all the small tubers and fleshy roots, otherwise these are certain to grow and impede the progress of the next crop.

Dwarf Beans.—In some gardens the forcing of Dwarf Beans is practised, and excellent crops are produced where the requisite temperature can be kept up, viz., about 60° Fahr. A vinery that is started will be a suitable place for the Beans, and Osborn's Forcing is still one of the best. Pots 8ins. in diameter are a useful size. They should be well provided with drainage and filled three parts of their depth with good quality loam and a little leaf-mould, with a moderate sprinkling of sharp sand. Place several seeds in each receptacle, and, finally, thin them to four or five strong seedlings. As growth advances, a top-dressing of rich soil should be afforded, and at no time must the roots suffer from lack of water. The atmosphere, too, should be kept fairly moist to prevent attacks of red spider. Later on the plants will need some support, and twigs from an old birch broom will be found suitable.

The Flower Garden.

Christmas Roses.—*Helleborus niger*, the Christmas Rose, is highly prized for its flowers, which appear in midwinter. These are greatly improved if a frame is placed over the plants just before the blossoms open. For a few isolated examples handlights will suffice. This plant enjoys a deep retentive loam and a partially shaded position, and as a rule may be left undisturbed for several years. In the spring and early summer the plants make their growth, and if the weather is at all dry the roots will need an occasional soaking of water, while two or three applications of liquid manure will be beneficial. If it is desired to increase the stock, division of the roots must be resorted to after the flowering season.

Bedding Plants.—The stock of summer bedding plants, which includes Zonal Pelargoniums (chiefly Paul Crampel), are here in heated pits and houses, and they will require frequent attention during dull damp weather to prevent loss from damping. All dead and decaying leaves must be removed, water be afforded in moderation, and a little air admitted whenever the weather is congenial. During a mild spell the lights may be open an inch or so throughout the night, with just enough heat in the pipes to cause a free circulation of the atmosphere. Well established cuttings may soon be potted off, and specimen plants should also receive attention. Begonia bulbs ought to be examined to ascertain whether any are rotten. If so, they should be removed forthwith.

Fruits Under Glass.

Vines.—If fairly early crops are desired, the first vinery, often containing Black Hamburgh, may be started into growth. Close all the ventilators and employ enough fire-heat to keep the temperature at 45°, this figure being raised 5° or so at the end of a fortnight. When the weather is bright sprinkle the paths and around the hot-water pipes with water.

The Early Peach-House.—If ripe fruits are required about May, the trees should be started into growth near this date. Hard forcing ought

not to be practised, the object being to encourage a slow growth, thereby affording the trees ample time to develop their flower-buds. A temperature of 40° to 45° at night is ample, with a rise of 5° when the weather is mild. During the day the temperature should not fall below 50°, but with sun-heat it can safely rise to 65°. A little top ventilation is needed when the temperature is high enough, and a close stuffy atmosphere should be avoided, especially at night. Damp the floor of the house twice daily when the weather is bright, but when the trees are in flower a drier atmosphere with a little more air is essential. See that the border is sufficiently moist, and watch for aphides on the young leaves. If these are present, lightly fumigate the house two nights in succession.

The Hardy Fruit Garden.

Blackberries.—For planting in odd corners or on boundary fences the various improved forms of the Blackberry are well adapted, or they may be grown and treated the same as Loganberries. A few good kinds are *laciniatus*, *Lawton* and *Wilson Junior*.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chesham, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Jerusalem Artichokes.—When lifting supplies, a sufficient quantity of second-size tubers should be retained and stored in sand or light soil for planting for next season's crop. Ground should also be trenched or dug to be in readiness for the crop, for planting should be undertaken early in the year; the plant requires a long period of growth for its full development. The white variety is considered superior to the red.

Horseradish.—Being almost indestructible, this invaluable accompaniment for roast beef gets little or no attention in some gardens, but the efficient cook knows the difference between the cultivated article and the other. To get fleshy thongs that can be easily scraped, Horseradish must be liberally cultivated and a succession of young plants kept up. Planting can, if the soil is at all in workable condition, be undertaken now. The best plan is to take out a trench from 2ft. to 2½ft. deep and fill it up with a mixture of the original soil and vegetable-mould with a layer of solid organic manure at the bottom. Select thongs of moderate thickness and cut them to a length of 6ins. to 8ins., retaining the crown end, of course. Pare off the centre bud just at its base, then plant the thongs in an upright position 1ft. apart with the crown about 1in. below the surface when finished.

Potatoes.—Look over seed stored in trays or boxes, removing any decaying tubers; see that rats or mice are not taking liberties with them. If necessary, protect these tubers, also ware in pits, from severe frost.

The Hardy Fruit Garden.

Pruning Fruit Trees.—If not already completed, an effort should be made to have pruning finished up by the end of the year, but the work should not be proceeded with when the shoots are frozen. Old standard trees which have been neglected may require to have some of the strongest limbs shortened with the saw. When this is the case the cut should be smeared with tar, Archangel tar being preferable to coal tar. Trees in the condition just described should also have been root-pruned according to directions given in this column on September 22, and if this has not been attended to, although now rather late in the season, it is advisable to tackle the job forthwith, thus saving another year's delay.

Liming Stone Fruits.—Stress has already been laid in this column upon the necessity for this attention, which has been more exhaustively dealt with by Mr. Macself in the issue for November 17, to which I would direct the attention of those interested. In applying lime, little and often is a sound maxim. Scatter the lime on the surface and simply cover it in with the rake. The operation should now be carried through without delay.

The Flower Garden.

Early-Flowering Gladioli.—Those who have to deal with heavy soils had better defer the planting of the corms of these attractive flowers until February, but on light, well drained soils planting may be undertaken right away if weather

permits. Should severe frost set in, a little loose protecting material should be afforded them.

Hyacinthus candicans (syn. *Galtonia candicans*) makes an attractive picture grown in conjunction with *Gladiolus bronchyleyensis*. Except on clay soils the tubers may be planted now; their position should be marked, as they are late in starting into growth.

Fuchsias.—Although old-fashioned, specimen Fuchsias are very effective as dot plants in large beds or as centre plants in small circular beds furnished with dwarf plants, such as *begonias* or dwarf *Antirrhinums*. These Fuchsias should be pruned now, spurting back the past season's growths. They require little or no water during the winter months; in fact, they can be laid on their sides under a cool greenhouse staging.

Leaf-Mould is a valuable asset in the flower garden, farmyard manure being too rich for many kinds of plant. The newly collected leaves should be formed into a compact heap, where they should remain undisturbed for a year, last year's crop being now available.

Christmas Decorations.—These will be somewhat shorn of their glory this year, in the North at any rate, for, from all accounts, the much-prized Holly berries are conspicuous by their absence. This lack of fruit is not peculiar to the Holly, but is characteristic of most berry-bearing trees and shrubs, and this is not to be wondered at after the abnormal crops which they bore in 1922. *Cotoneaster Simonsii* is one of the few berry-bearing shrubs which has fruited well up to its usual standard, and the deft fingers of the experienced decorator will manage so to intermix it with the Holly as to make a decent show. The variegated Hollies, *Golden Queen* and *Silver Queen*, will help to brighten things up. Ivy can also play an important part in the Christmas decorations; long trails of the Common Ivy, *Hedera Helix*, may be used with good effect in draping pictures, etc., and by entwining it round the stair bannisters. Some of the small-leaved varieties, such as *H. H. cuspidata minor*, can be usefully employed arranged on the cloth of the dining-table, and will be a change from the usual *Smilax* and *Asparagus*. The choice of a Christmas tree lies between the Scots Pine, Common or Oriental Spruce and English Yew.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Chrysanthemums.—The stock plants should be stood in cold frames. To keep the shoots strong and sturdy they should be afforded plenty of air on all favourable occasions. Where it is desired to grow large specimen blooms, a start should now be made with propagation. Although it is still too early to make a real start with the decorative varieties, one should not miss securing strong, sturdy cuttings, which can often be obtained at this time, as such shoots in a few weeks time would be too long, and so useless for propagating purposes. Inserted now they can be stopped several times in the young state, and thus lay the foundation for large bush plants. Cuttings can be rooted, too, from the young plants later on. This double rooting is, in fact, the best way to treat some varieties which give rather hard cuttings now. If the tops of the newly rooted plants are "taken" later on in the season, the resulting plants seem to grow away much more freely. With varieties that are poor stockmakers it may be advisable to place the stock plants in gentle warmth to encourage the production of cuttings. Wherever possible, cuttings should be taken from the base of the plants, as shoots produced from the hard stem generally make poor plants. To grow plants in 6in. pots for the stages, March is early enough to take the cuttings. As it is undesirable to retain old stock-plants until then, it is the usual practice to root for the purpose the tops of young plants that were propagated earlier in the year.

Eucalyptus globulus is, in the young state, very useful for grouping with other plants in the conservatory. For this purpose it is best raised from seed each year, and a pinch of seed may be sown at this time. It germinates readily in a house with an intermediate temperature (say about 50°).

E. citriodora.—It is worth growing a few plants of this species in pots for the greenhouse, as the foliage is very fragrant, resembling that of the lemon-scented *Aloysia citriodora*. Young

plants of *E. l. Connii* and *cordata*, both with beautiful silvery foliage, are also very useful for decorative work.

Grevillea robusta.—This elegant plant in its young state is very popular for decorative work. Where plants are required in quantity it is wise to make several sowings in the course of the year. Apart from its use for decoration, young plants are very useful as stocks upon which to graft some of the choicer species of *Grevillea*, such as *G. G.*, *punicea* and *oleoides*, which are difficult to propagate from cuttings. The thin flat seeds of *G. robusta* are very apt to rot when sown in the usual way, and it is wise to set them on edge. I have also found them germinate freely if left quite uncovered, always provided that the seed-pots are kept in a warm, moist atmosphere. A little seed may be sown at this time, and another sowing be made early in the New Year.

Fatsia japonica (syn. *Aralia Sieboldii*).—This plant, although hardy in most parts of Britain, is very useful for decorative work in the conservatory and dwelling-house, for which purpose small plants are generally most useful. There are two variegated varieties of this plant, one with white and the other with rich golden yellow variegation, neither of which is hardy in any case. *F. japonica* is easily raised from seed, and is also propagated by means of root cuttings. Pieces of root may be cut in 2 in. lengths and dibbled into pots or pans of sandy soil, leaving the tops of the cuttings just exposed. The pots should then be placed in a close case with slight bottom-heat at command. The stems may also be used for propagation, as each eye is capable of growing and producing a plant, in which case the stems, cut into sections, should be laid in a bed of fibre in a propagating-case.

Freelias should be kept neatly supported, for once the shoots are allowed to fall over they never grow freely again. The most forward plants should be given a light position well up to the glass in a sunny greenhouse; later batches may remain in cold frames until they require more head room. The same remarks apply to *Ixias*, *Tritonias* and *Lachenalias*. Although they all do quite well in cold frames, especially in their earlier stages, still where room can be spared they are best transferred as growth advances to a bright airy greenhouse. Thus treated, a freer circulation of air can be obtained, and the growth be kept stronger and more sturdy. *Freelias* when doing well and in full growth are free-rooting plants, and benefit by weak applications of liquid manure or soot water, but such manures should be fresh. When in a stale condition they may prove harmful to the plants.

Royal Botanic Gardens, Kew.

J. CUTTS.

The Rosemary-Leaved Gromwell.—Though generally considered tender, the beautiful *Lithospermum rosmarinifolium* is quite hardy enough for outdoor culture in any but our bleakest counties. It needs, of course, a sunny, sheltered corner with a well drained, stony soil, and if it can be given the shelter of some overhanging bough which will throw off white frosts without obstructing the winter sun so much the better. This is suggested because it is not so much the actual hardness of the shrub that one has to fear, but the effect of the frost upon the blossoms, which open in midwinter. A native of the cliffs of Capri and Naples, it makes a neat, somewhat dense little shrub about 15 ins. or so in height and as much across. The foliage, as the name suggests, is not unlike that of the Common Rosemary, but it is a richer, glossier green and closer in growth. The flowers, which are borne in clusters at the tips of the shoots, are large (often 3 in. across) and of a blue so pure and intense that few of the *Gentians* can rival them in colour. The species is a lime-lover but, beyond that, its wants appear to be few, for it will thrive in the hottest and poorest soil and drought has no terrors for it.

A Useful Carpet.—For covering the ground or growing in little colonies between any thin-habited *Ericaceous* plants which need such company *Druckenthalia spiculifolia* can be recommended. This is a pretty little heath-like shrub, barely 6 ins. in height, with a very dense, dark moss green foliage and erect flower-stems bearing,

about midsummer, terminal heads of pale pink blossoms. *B. spiculifolia*, a native of Eastern Europe, is perfectly hardy and a good doer under any conditions which suit the *Ericaceae*. It also makes an attractive plant for a cool peaty pocket or ledge in the rock garden, where its cushion of green will be an attractive object at any season. Though *B. spiculifolia* bears so close a resemblance to the *Heaths*, it differs from the true *Ericas* in the corollas of its flowers, which open wide at the mouth instead of being pitcher-shaped.

Campanula Zoysii.—To the *Campanula* lover *C. Zoysii* always appeals. His admiration for the race is eclectic enough to appreciate even some far less worthy of his affection than this quaint little gem, which has, besides, for the collector the added distinction of not being too common in gardens, although the true flower-lover does not consider that a factor at all. To see a good plant of *C. Zoysii* in autumn is, however, to admire it and to enjoy its little carpet of leaves, which late in the season are adorned with a multitude of small hanging bells of the quaintest shape among these dwarf *Bellflowers*. They are shaped after a fashion likened, somewhat irreverently it may be, to soda-water bottles, and one writer has even gone the length of adopting this description with the addition of a mouth like a ham frill. It does seem a little disrespectful to such a charming *Campanula* to speak of it in this way, yet, after all, if we are to adopt common phraseology to convey its portrait to the mind of the reader who knows not the plant, then we may agree to let it stand. It is exquisite with its deep blue miniature bells on thread-like stems and so quaintly shaped as to be interesting in themselves. As for its culture, there is no doubt that it does give trouble, although this is denied by some. The main source of the discomfiture of the grower is the slug, which has an insatiable appetite for *C. Zoysii*. A good plant may disappear in a day or two, and it is difficult to ward off these enemies. We have known good plants doing well in gritty soil, and it is a success on the moraine, but the slug is its potent enemy and, short of a notched zinc ring, there is little which will prevail against this foe.

Saintpaulia ionantha.—One of the most delightful plants that is now in flower is *Saintpaulia ionantha*, sometimes known by the simpler and more attractive name of African Violet. The flowers, which are somewhat like the Violet, from which it takes its name, are borne in wonderful profusion on stems 3 ins. high and, better still, continue without interruption until well into March. These points, combined with its season of flowering, make it one of the most desirable plants where a winter temperature of 55° to 65° can be provided. The seeds are very minute and need care in raising until the plantlets are of some size, otherwise they cannot be described as difficult. Prick them off, when large enough to handle, into seed-pans, and when the leaves begin to touch each other they will be ready for small pots. They are not particular as to soil, provided it is light and rich and has a certain amount of sand in it. Perhaps the best effect is provided by growing several plants together in a shallow seed-pan and using a number of these to decorate the edges of the staging. Through the summer a temperature of 45° to 55° is ample to grow them well, for it is not until autumn and winter come that the greater heat is required to expand the buds. Take care that the plants enjoy plenty of light. Direct sunshine they cannot stand, but it is a mistake to suppose that they will flourish under heavy shade. After flowering, one of two courses may be followed. Either the plants may be split up and divided or each leaf, if pegged down, will soon form a wee

plant that may be detached and treated precisely the same as a seedling.

The "R.H.S." Gardeners' Diary.—The diary for 1924, just to hand, is, as usual, an excellent little production, exactly similar in outward appearance, except as regards colour—which is crimson—to last year's issue. There have been some changes, however, in the table of contents. There are now included notes on Brooms, which, however, seem rather partial inasmuch as no species of *Genista* is recommended; on Climbing Roses for Autumn Blooming; Croquet Courts; Lining Soils; Postal Rates (which should certainly be made a permanent feature); Potato Spraying; Sowing a New Lawn; and Sweet Peas. The amount of tabloid information given is, in fact, quite remarkable; none surely exceeds in value that on the pruning of flowering shrubs, now, apparently, a regular and permanent feature. This is, in short, one of the cheapest diaries we know and, for a gardener, incomparably the best. The diary is published by Messrs. Charles Letts and Co., Southwark Bridge Buildings, London, S.E.1, and the price is 2s. net.

British Empire Exhibition Tulips.—Over 5,000 *Delphiniums* have already been planted out in the grounds of the British Empire Exhibition at Wembley, and over 100,000 of the finest British-grown Tulips will be on show in May of next year. This collection of Tulips will be a very beautiful and comprehensive one.

Trial of Brussels Sprouts at Wisley.—The following awards have been made to Brussels Sprouts by the Council of the Royal Horticultural Society after trial at Wisley: Awards of merit.—Solidity, sent by Messrs. Wheeler, Warminster; One and All, sent by Mr. F. C. Heinemann, Erfurt, Germany; and Darlington, sent by Messrs. Nutting, 106, Southwark Street, London. Highly commended.—Standard, sent by Messrs. Barr, King Street, Covent Garden, London; Half Long Paris, sent by Messrs. Toogood, Southampton; Walton Dwarf No. 12 and Walton Dwarf No. 2, both sent by Messrs. W. Rowlands and Co., Childwall Nurseries, Liverpool. Eight other varieties were "commended."

R.H.S. Rose Judging Committee.—The Council of the Royal Horticultural Society has invited the following to form a Judging Committee for their new trials of garden Roses for garden purposes, and all have accepted the invitation: Chairman, the President of the R.H.S., the Right Hon. Lord Lambourne, P.C., V.M.H., the chairman of the Wisley Committee, Mr. W. Cuthbertson, J.P., V.M.H., Mrs. Wightman of Bengoe, Messrs. Wettern, Holland, Darlington, Drs. Lamplough and Williams, Messrs. Easlea, Prince, G. M. Taylor, A. Dickson, jun., Hays, Coutts, Pernet Ducher and S. Poulsen.

A Correction.—The illustration appearing on page 641 of the issue for December 8 is of *Silene acaulis*, not of *S. alpestris*, as stated. Many readers will, no doubt, have noticed the slip. *S. alpestris* has, of course, small fringing white flowers on 3 in. wiry stems and is quite dissimilar from the plant illustrated.

Answers to Correspondents

ROSE GARDEN.

HARDY AND VIGOROUS ROSES (Dunmow).—In our correspondent's list the following varieties are the most vigorous: Hoosier Beauty, Mrs. Edward Powell, Covent Garden, J. G. Glassford and Fisher Holmes. As regards hardiness there is not much difference in them; the variety Edward Mawley being the tenderest.

NAME OF FRUIT.—J. E. J.—Apple Royal Late.

NAMES OF PLANTS.—Mrs. L. B.—*Bambusa palmata*.—C. S., Spain.—1, *Maclura aurantiaca*; 2, *Phytolacca dioica* (syn. *P. arborea*); 3, *Stereulia diversifolia*; 4, *Jasminum humile*. H. A. G.—A, *Thuya orientalis* var. *melanensis*, B, *T. o.* var. *globosa*.

Irish Roses of Matchless Beauty

WE are admittedly the world's Leading Raisers, and our Guaranteed Irish Grown Roses are the finest that skill and the briar can produce. McGredy's blooms have long since won the approbation of the Royal Family, and have been awarded alone 45 Gold Medals of the National Rose Society.

THE PRIMULAS OF EUROPE

With Botanical Classification, Descriptions, and
Cultural Instructions

By JOHN MACWATT, M.B.

Crown 8vo., Cloth, 12/6 net; Postage 9d. extra.

The aim of the author has been to produce a handbook that will assist in the identification of those species of the genus Primula which are native to the European continent, and at the same time furnish practical guidance to the cultivation of such of them as have been introduced to our gardens where conditions differ so widely from those prevailing in their natural habitats.

Dr. MACWATT is an acknowledged authority on Primulas, and his book presents in a concise and interesting manner the results of many years of close personal observation and experience.

NEW SPRAYING MACHINES LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete without a Sprayer, in fact a Sprayer is absolutely essential to obtain best results.

During the War we supplied a considerable number of our well known Four Oaks Knapsack Sprayers—Rubber Diaphragm type—to the Government, and we have just re-purchased a small quantity back again, which have never been used. They are

made of copper but painted Service grey colour. They have various special additions to the ordinary machines, and the price to-day would be £5 each. We guarantee them to be in perfect working order as new. We will send one machine carefully packed, carriage paid, on receipt of 50/-, but cash must accompany all orders. We would supply 2 machines for 90/-, carriage paid.

Please mention this Paper when ordering.

GLASSHOUSES.—CARTER & HOWARD, Raynes Park, S.W.20. 'Phone: Wimbledon 2377.

CHOICE NEW CHRYSANTHEMUMS.—Our Catalogue of nearly 800 varieties, including splendid novelties for 1924 (also new Dahlias, Pelargoniums, &c.), is now ready. Post free. J. W. COLE AND SON, Chrysanthemum Specialists, Peterborough.

COVERING EVERYTHING, MENDING EVERYTHING and REFASHIONING EVERYTHING, three booklets full of practical hints and useful information by M. STUART MACRAE, and published at 9d. each (postage 1½d.) at the Offices of "COUNTRY LIFE," LTD., 20, Tavistock Street Covent Garden, W.C.2.

THE DOG: MAN'S FIRMEST FRIEND.—How to choose and care for him, by A. CROXTON SMITH. A copy of this helpful booklet on the housing, breeding, feeding and care of dogs will be sent post free on receipt of 11d., addressed to The Manager, "COUNTRY LIFE," LIMITED, 20 Tavistock Street, Covent Garden, W.C.2.

VEGETABLE GROWING.—"A Vegetable Grower's Handbook," by Fanny Bennett and E. S. Rohde.—"A sound Practical Guide," says the *Field*. Price 2/6 net. Post free 2/9.—MARTIN HOPKINSON & Co., LTD., 14, Heorietta Street, London, W.C.2., or all Booksellers.

HOME-BREWED WINES AND UNFERMENTED BEVERAGES for all seasons of the year. By ANNE AMATEUR. A helpful booklet containing also recipes for invalid drinks, and published at 9d., post free 11d., at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, W.C.2.

PLANT PESTS AND PARASITES.—A useful booklet on garden troubles by HORACE J. WRIGHT is to be obtained from the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, W.C.2; 11d., post free.

ELLISON'S PEDIGREE SEEDS cost no more to grow than ordinary strains. Prices most reasonable. Government germination guaranteed; therefore grow ELLISON'S PEDIGREE SEEDS. When doing so you are buying from a firm established 1890. Regular Exhibitor at the principal shows; 46 Gold Medals awarded. 64 page Catalogue free. SEEDS, BULBS, ROSES, FRUITS, FERTILISERS. Shallots, 6d. lb. G. & A. Fertiliser, 5s. cwt., Broad-leaf Privet, 15in., 12s. 100. Scotch Seed Potatoes, 11s. cwt.—ELLISON'S SEEDSMEN, WEST BROMWICH.

BARR'S SPECIAL OFFER OF SURPLUS SPRING-FLOWERING BULBS. Daffodils, Hyacinths, Tulips, Crocuses, Snowdrops, etc. All selected bulbs in fine condition at greatly reduced prices. List on application.

BARR'S SURPLUS HARDY PLANTS for Flower Border and Rock Garden, including fine selections of Irises, Michaelmas Daisies, Aubrietias, Helleborus, etc., etc. List on application.—BARR AND SONS, King Street, Covent Garden, W.C.2.

THE DOUGLAS CLOVES.—Our wonderful new strain of Hardy Border Clove Carnations again won the Large Silver Cup at the R.H.S. at the Great Chelsea Show, June, 1923. We have now won more Awards of Merit of Royal Horticultural Society for Carnations than any other two firms together. Rigid stems, perfect calyx, glorious scent. New plant list.—DOUGLAS, Edenside, Bookham.

SUTTON'S

RECORD IMPROVEMENTS IN GARDEN PEAS

THE history of the Garden Pea is one of constant improvement and now under proper cultivation, and by the choice of suitable varieties, delicious Marrowfat Peas may be picked during 7 months of the year.

Such wonderful improvement has been achieved by years of patient cross-breeding and selection and the Garden Pea of to-day bears no resemblance to the poor varieties of former times, either in size or quality. In no variety is this advance more marked than in our well-known V.C. — the largest-podded Pea in cultivation, or Phenomenon, the giant-podded dwarf.

Full particulars of all the best Peas will be found in our Garden Seed Catalogue for 1924 -- free on application.

[DECEMBER 29, 1923.]

THE PICK OF THE SILENES

THE genus *Silene* (Catchfly) belongs to the Pink family (Caryophyllaceæ) and comprises, according to some authorities, about 400 species. It is probable, however, that many of these so-called species have no validity, but the genus certainly includes some of the most ornamental and useful border and rock-garden plants. It comprises annual, biennial and perennial herbs, distributed over the greater part of Europe, North Africa and Temperate Asia, with about twelve in South Africa and eighteen in North America. They range in height from the little Moss Campion (*S. acaulis*), forming dense little hillocks of pale green foliage, from which the pink flowers scarcely raise their heads, to the handsome white-flowered *S. fimbriata*, which grows about 3ft. high. The former type, of which there are several species, supplies beautiful little plants for the rock garden or moraine, which are not difficult to cultivate, providing they get ample drainage, a sunny position, and plenty of moisture during the growing season. The larger border kinds will thrive in any light loamy soil. Of annuals the genus contains a large number, many of which are very ornamental. One of the best known is *S. pendula*, which is grown extensively in the spring flower-garden. It should be treated as a biennial and sown in the autumn, and will then produce bushy plants, covered in spring with a profusion of beautiful pink flowers. All are increased by means of seeds, while the perennials may in addition be propagated by division. Cuttings of the smaller kinds, like *S. acaulis*, root readily in summer if inserted in sandy soil in a close frame or under a bell glass. Some of the best are:

***S. ACAULIS*.—**The Moss Campion, or Cushion Pink, is one of the most charming members of a genus that contains a large number of attractive plants. In the Lake District and on some of the Scotch mountains, as well as on the Snowdon range in Wales, this delightful plant is found growing wild, forming dense cushions of foliage covered in spring with rosy pink flowers. Growing in rough stony ground on the Turtman moraine in

the Valais, at an elevation of 8,000ft., I have met with tufts measuring more than 1ft. in diameter, covered with sheets of bloom. Other tufts of various sizes, equally densely flowered, were growing in profusion all over the place, making a most attractive display of colour. There are several varieties of *S. acaulis* in cultivation, including *alba* with pure white flowers, and *aurea*, which has tufts of leaves of a golden hue. Generally speaking, the flowers of *S. acaulis* are produced on short stems close to the foliage, but there is a stronger-growing and larger-flowered variety called *elongata* which has darker-coloured flowers on short stems raised well above the tuft. Another

name for the last is var. *grandiflora*, and it is also met with in gardens under the name of *S. saxatilis*. *S. acaulis* var. *flore pleno* is a double-flowered form which has the advantage of being more lasting than the single ones. The main essential for success is a moist, deep, gritty soil in a sunny position.

***S. ALPESTRIS*.—**A choice little perennial which makes a dwarf spreading carpet is the pretty Austrian or Alpine Catchfly. Only from 4ins. to 6ins. high, the stems are freely produced, and bear a profusion of pretty white flowers in May, and it continues in bloom for a long period. It is a useful plant for growing in pans for the alpine house. A native of high moist rocks in the Austrian Alps, it has been grown in gardens over a hundred years. With the closely allied *S. quadrifida* and *S. monachorum*, *S. alpestris* forms a distinct section of the genus *Silene* to which some authors apply the name *Heliosperma*.

***S. ARMERIA* (Sweet William Catchfly).—**A very ornamental annual or biennial species with crimson rose flowers in dense heads from May to August. The glaucous foliage is very characteristic of the plant, which is valuable for naturalising on old walls and rocky banks, where it will soon establish itself. It grows up to 1½ft. high and is a native of Western Europe. *S. compacta* is a good-flowered form of this with larger, denser heads.

***S. ASTERIAS*.—**This grows about 1ft. high, with carmine-scarlet flowers in large compact heads, which have been compared to Scabious in appearance.

***S. CALIFORNICA*.—**A beautiful plant from California, where it grows at an elevation of from 1,300ft. to 3,000ft., generally in woodlands, associated with Oaks and Douglas Fir. Here the soil is gravelly, but rich in humus, and the plants root very deeply into it, sometimes going down quite 18ins. The plant spreads by means of underground branches, and forms tufts about 3ins. high, from which arise the beautiful scarlet flowers on branching stems 6ins. or more in height. A sunny position and perfect drainage is essential for its well-being.

A USEFUL BIENNIAL, *SILENE ARMERIA*.

S. LACINIATA.—One of the long-stemmed members of the alpine section, this is a tufted plant with lanceolate leaves 2ins. or 3ins. long. The stems are ascending, some 6ins. long, and bear several bright rose-coloured flowers, 1½ins. in diameter, in July. It comes from Northern Italy, and is easily grown in gritty soil. One drawback to this beautiful species is that some forms are self-sterile, and have little or no petal but produce plenty of seed.

S. TIMERIATA.—A handsome border plant 3ft. to 4ft. high, with erect stems clothed with undulated, narrowly ovate leaves. The white, fringed flowers are borne in large spreading panicles from May to August. Native of the Caucasus, it is an easily grown perennial well worth a place in the border.

S. FORTUNEI.—This Chinese species is one of the most elegant plants in the whole genus, and is especially valuable as an autumn-flowering plant. It grows to a height of between 2ft. and 3ft., and as it branches freely, forms a compact bushy plant covered with loose panicles of erect flowers. These vary from very pale to rose red in colour, are about 1½ins. in diameter, and have deeply lacinated petals. Although it is a perennial and will survive the winter, the best results are obtained from plants the seeds of which have been sown in heat early in spring and the young plants put out as soon as large enough. They grow rapidly in any light rich soil during the summer, and commence flowering in the month of September. It is said to be a common Chinese plant, and was first found by the traveller Fortune, after whom it was named; but it was not introduced into this country till the year 1868. Seeds of it were sent home then from the province of Shensi by Father Piccoli. Like so many other members of this family, the stems are covered on the upper portions with a viscid substance, rendering the plant sticky to the touch.

S. HOOKERI.—This handsome species is a native of California, and the honour of its introduction rests with the late Mr. Thompson of Ipswich, who received seeds of it from Professor Bolander in 1873. It flowered with him and was figured in the *Botanical Magazine* at the time, but for some reason, probably due to lack of knowledge as to its requirements, the plant was lost. About ten years ago it was reintroduced by Mr. Carl Purdy, and now is represented in many gardens. *S. Hookeri* is one of a small group, all natives of California and the Western United States, remarkable for their brilliantly coloured flowers. Others of this group are *S. laciniata* and *S. californica*. *S. Hookeri* is usually found growing on wooded hillsides, and is described as having both white and rose-coloured flowers. It is a tufted plant with somewhat lax, short, decumbent stems, and is very free-flowering in habit. The oblong, lanceolate leaves are 2ins. to 3ins. long, and the whole plant is softly pubescent or almost woolly. The rose-coloured or pink flowers are over 2ins. across, each petal being four-cleft, while the under-sides of the flowers are of a light buff shade. *Silene Hookeri* is easily raised from seeds, and soon makes plants fit for planting out. A warm sunny spot should be selected, taking out the soil to a depth of 1½ft. This may then be filled with broken bricks at the bottom, with a sharp gritty compost on the top consisting of a mixture of loam, leaf soil and granite chips. The latter are not essential, as it will also do in lime. In such a position it may be established and prove a good perennial, flowering freely during the summer each year.

S. LACINIATA.—Another Californian plant of great beauty, this has narrow green leaves, somewhat woolly, a very graceful-spreading habit, and flower-stems rising to a height of about 6ins.

THE SUN-LOVING SILENE HOOKERI.

A DISTINCT FORM OF *S. ACAULIS* IN ALPS.ANOTHER FORM OF *SILENE ACAULIS*—VAR. *PEDUNCULATA*.

These are branching, and bear numerous flowers of a rich cardinal red during the summer months. The species requires a dry position, as, like in *S. Hookeri*, the roots are thonglike, growing very deep and having a preference for stony positions or deep crevices between rocks.

S. NOCTIFLORA.—This night-flowering *Catchfly* is an annual, growing up to 2ft. high, with branching stems and large fragrant flowers. The petals are pale rose-coloured, or nearly white within, and yellow outside. It flowers in July and August, and is a native of this country.

S. PENDULA.—A much-branched pubescent annual or biennial, this produces masses of pink flowers from May onwards. It is a native of Italy and a well known garden plant.

S. PENNSYLVANICA (American Wild Pink).—A pubescent perennial, growing about 6ins. high, with branching stems and short-stalked pink flowers in clusters, this will thrive under the conditions advised for *S. laciniata*. It commences to flower in May and, when doing well, remains in blossom well into July.

S. PUMILIO.—One of the gems of the genus, this is a beautiful, dwarf rock plant with tufted foliage similar to the Moss Pink, but the leaves are rather longer. The flower-stems are only 1in. high and bear solitary flowers 1½ins. across. These have clawed petals with a broad blade, and are pink in colour, borne during the summer months. It should be grown in the moraine, succeeding under conditions suitable for *S. acaulis*. Grown in gardens since the year 1823, it is a native of the Tyrol, where it grows in the crevices of high alpine rocks.

S. REGIA (Royal *Catchfly*).—Hailing from the Southern United States, this is a handsome pubescent perennial with erect stems 3ft. high, clothed with narrow ovate leaves. The deep scarlet flowers are borne in clustered panicles in July. It is easily grown in a half-shady border, and ripens seed freely, but is not common in gardens. This is due, perhaps, to the fact that it suffers in our damp and changeable winters.

S. SAXIFRAGA.—This is a low-growing tufted rock plant suitable for a sunny pocket or ledge. It makes an evergreen carpet with linear leaves and bears numerous flowers from June to August. These are yellowish within and reddish brown on the underside of the petals. A very easily grown plant, it is a native of South Europe, and has been in cultivation nearly 200 years.

S. SCHAFTA.—A beautiful little perennial with a woody root and many interlacing stems not more than 4ins. high, it produces during the whole of the summer months a succession of rosy purple flowers. It is an excellent rock plant, revelling in a sunny crevice or on a rocky ledge. It produces plenty of seeds and is easily raised.

S. VIRGINICA.—One of the brightest and most showy members of this genus is the Virginian Fire Pink. Although appropriated by its name to Virginia, it is not exclusively confined to that State, but is found in several others, growing in open woods on rocky hills. It was first introduced into this country more than a hundred years ago, but, like many other good things, it requires a little care to grow successfully, and so has not become common in gardens. Very liable to suffer from damp in winter, it likes partial shade and a well drained position in sandy gritty loam. In such places it produces its flowers freely from June to August. The stems vary in height from 1ft. to 2ft., are tinged with a red-brown colour, and have two or three pairs of opposite leaves about 4ins. long. The brilliant crimson or scarlet flowers are large and star-like, the larger ones 2ins. in diameter. Each petal is divided at the apex into two lobes about one-third of its length, and these, again, have each a small one on the

outer margin. Sticky to the touch, like many other species, this is closely allied to *S. pennsylvanica*, a much dwarfier kind.

S. ZAWADZKII.—A useful plant for the rock garden, this has a woody rootstock, tufts of leaves 3ins. long and 1in. broad, and white flowers in

dichotomous racemes on stems about 6ins. high. It produces its flowers freely during the months of May and June, and is one of the most easily grown of the smaller *Silenes*. It is a native of Eastern Europe, where it grows at about 6,000ft. elevation. W. I.

FURTHER NEW ROSES OF 1921

I WAS⁴ able last year to describe most of the British Roses of 1921, from such leading firms as McGredy, Alex Dickson, Frank and B. R. Cant, etc., but a few we had not succeeded in obtaining came in for testing

a year later, together with the bulk of the Continental novelties. The British productions were:—

ADONIS (H. T., Bees, Limited).—The blooms are pale yellow and fragrant, but hardly heavy enough for exhibition. It makes good, clean growth, about 12ins. high. Award of merit, National Rose Society.

ARIEL (H. T., Bees, Limited).—This is a small and thin orange yellow buttonhole Rose, its height about 12ins. The growth is bushy. Award of merit, N.R.S.

ARGYLE (H. T., Dobbie and Co.).—The blooms are flat and of creamy colour, the growth good, about 18ins. high, and the leathery foliage excellent, in fact, growth and foliage are better in their way than the blooms, which are disappointing.

DAINTY (H. T., Hugh Dickson, Limited).—This is a pretty bi-colour Rose, described as apricot pink, after the style of Countess Clanwilliam, though thinner and of deeper colouring. It is not a strong grower, only making plants about 12ins. high. It has good foliage.

DIANA (H. T., Bees, Limited).—The blooms remind one of Mrs. F. Dennison and should be heavy enough for exhibition. It makes strong growth, about 18ins. high, and has good foliage.

DOROTHY HOWARTH (Dwarf Poly., Bees, Limited).—When these so-called dwarf polyanthas attain heights of over 18ins. they might really be classed as polyantha bush Roses. This is from Leonie Lamesch x Anchen Muller. The very heavy trusses are of coral pink colour and the foliage excellent.

EMMELINE (H. T., Wm. Paul and Son).—Deep yellow buds open out to flat white blooms. It is a very strong grower, 2ft. high, with strong, dark-coloured foliage. A free-flowering, decorative Rose, it is best suited for shrubberies, etc.

FLORENCE (H. T., Wm. Paul and Son).—It has pink blooms and that is about all that can be said for it. Growth is strong, about 30ins. high. New Roses of this type are not wanted; they are no improvement on existing varieties.

J. G. GLASSFORD (H. T., Hugh Dickson, Limited).—The velvety crimson blooms are sweetly scented and the strong, upright growth about 15ins. high. This certainly looks a promising new variety, and shall be tried again. Gold medal, N.R.S.

THE DEEP CRIMSON J. G. GLASSFORD.

LEONORA (H. T., Wm. Paul and Son).—New Roses like this should never be allowed to be put on the market. The colour is red, turning blue on maturity, the blooms are flat in shape and growth is stunted. Yet it is catalogued as "Velvet crimson, centre fiery red; large and full, globular, vigorous, garden and exhibition." Oh! those catalogue descriptions! A censor is badly wanted.

MACBETH (H. T., Bees, Limited).—A bright crimson buttonhole Rose—a pretty little thing about 15ins. high, with rather thin blooms. It has dark foliage.

MARGARET M. WYLIE (H. T., Hugh Dickson, Limited).—The buds are long and pointed, the blooms very thin, light pink, opening semi-single. The growth is erect and tall and about 2ft. high. This, with its large trusses of big blooms, should be a good bedding Rose.

MARJORIE BULKELEY (H. T., Hugh Dickson, Limited).—The blossoms are light pink, but too flat. The growth is good, about 2ft. high. the

foliage large leaved, dark and leathery. It wants trying another year before pronouncing finally on its merits as a garden Rose. Gold medal, N.R.S.

MARCO (H. T., Wm. Paul and Sons).—The blooms are pink and orange in July, while in August they are almost identical in colour with those of Los Angeles. It throws big trusses of bloom and good, dark foliage, and is of erect growth, 2 ft. high. This is a novelty which certainly looks promising.

PORTIA (H. T., Bees, Limited).—The blooms, though small and thin, are quite a unique nasturtium-red colour. The growth is excellent, about 15 ins. high. This is another promising variety. Award of merit, N.R.S.

PECK (H. T., Bees, Limited).—The blossoms, which are pink to carmine are, unfortunately, flat and apt to lose colour, though the scent is good. The plant throws big trusses of bloom. Height about 15 ins.

SYBIL (H. T., Bees, Limited).—The deep pink blooms are of good shape and after the style of Mrs. Henry Morse. They last quite a long time on the plant, and autumn blooms are profusely borne and of the same good shape and colour. This is a very promising novelty. The height is about 15 ins. Award of merit, N.R.S.

VENUS (H. T., Bees, Limited).—The flowers are salmon pink and fragrant, the growth thin and about 2 ins. high. The blossoms are not heavy enough for exhibition, but it should prove an excellent garden variety. Gold medal, N.R.S.

Summarising these there is nothing really startling or conspicuous either as novelties or improvements. Some can be eliminated forthwith, others will be given another year's trial, when it will be possible to pronounce a more definite opinion on their merits.

NEW 1921 CLIMBERS (FOREIGN).

ALBERGINE (Wich., Barbier).—Origin Wich. & Mrs. A. R. Waddell. This has not bloomed yet, but is reported to be a good coppery colour. The growths are strong, though none too tall yet, the foliage dark and leathery and, with us, inclined to shew signs of mildew.

FRAICHEUR (Wich., E. Turbat).—This bears pretty small pink blooms, like those of Lady Godiva, though brighter. The growth is not very strong. The leaves are small, but clean and good.

CLIMBING MME. EDOUARD HERRIOT (Cl. Perpetua, Ketten Frères).—This is reported to be an improvement on its parent, in that the blooms hold their heads up better. The growth is good, but so far not tall.

VIOLETTE (Cl. Poly., E. Turbat).—A violet cluster Rose, similar to Veilchenblau, but of a brighter colour. Do we want more violet Roses? The foliage is good and the growth fair—not tall.

Another year's trial when the blooms can be fully examined and reported upon will decide which of these new climbers, if any, are to be retained.

HERBERT L. WETTERN.

THE SAURURACEÆ

HOUTTUYNIA CORDATA is an interesting herbaceous plant with something the habit of a dwarf Polygonum, spreading by means of rather thickened rootstocks or underground stolons, but, unlike many other plants of a similar habit, its growth is not too aggressive. The upright, grooved, flexuose, leafy stems are usually unbranched and from 4 ins. to 1 ft. in height. They

are terminated by an involucre which consists of four white, oblong, obovate spreading petal-like bracts inserted immediately below the erect cylindrical spadix, or spike, which is from ½ in. to 1 in. in length, and bears the naked, minute flowers with conspicuous golden stamens closely packed together. The fruits are ovate triangular and terminate in three recurved styles. The cordate-acuminate leaves are alternate, purple

when young, turning green later, and furnished with a membranaceous, brown, somewhat ciliate stipule at the base of each petiole. The illustration is of a clump growing in the water garden in the Botanic Garden, Cambridge, where it not only grows along the edge of the water, but for some distance up a bank that is somewhat dry. It flowers from June onwards—sometimes till October, and is readily raised from seed or increased by division of the root; division is best carried out in spring, when growth commences.

It was first discovered by Thunberg in Japan, where he found it very common in the ditches between Mito and Jedo, flowering in May and June. It is known in Japan as *Dokee Dami*, or *Sjunjak*. It was also found by *Loureira* in the gardens of Cochin China, where it is eaten as a salad. It has since been found by others growing very plentifully in Nepal and other hilly districts in India. In the Khasia Hills in Assam it is relished as a food both raw and cooked. It was named after Dr. Houttuyn of Amsterdam, a well known writer on natural history.

Houttuynia belongs to the family Saururaceæ, an interesting group of plants which consists of three genera and four species. This group was at one time included in Piperaceæ, the Pepper family, but is now generally separated, as there are several differences both in the flowers and in the anatomy of the stem. The chief differences are that in Saururaceæ the vascular bundles are in one ring only, while in Piperaceæ they are arranged in several rings, and that while in Saururaceæ there are numerous sutural ovules, in Piperaceæ there is only one basal ovule.

Anemopsis californica, a native of California, is sometimes included in Houttuynia, but it is generally considered distinct enough to be separated. It is an interesting perennial plant, spreading by means of runners, the leaves are produced in tufts, and the spreading white bracts are six in number, the three inner ones being spotted with red.

Saururus cernuus and *S. Loureiri*, the remaining two members of this group of plants, are also well worth growing, and with the preceding two make an interesting group, all of which are hardy enough to be grown outdoors in most parts of this country, but are, nevertheless, seldom seen.

Botanic Garden, Cambridge. F. G. PRESTON.

A BEAUTIFUL DWARF RHODODENDRON

ONE of the most delightful of the dwarf Rhododendrons is *R. (Azalea) ledifolium*, which, though closely allied to the indoor *R. indicum*, is perfectly hardy in any sheltered place. This is an evergreen shrub, seldom rising above about 4 ft. in height in most gardens, and often remaining for years at half that stature, though it may cover a square yard with its spreading branches. The small and numerous leaves are a pale green and hairy, and the flowers, which are borne abundantly in small trusses, or singly, in May, are over 2 ins. across, pure white and deliciously fragrant. *R. ledifolium* will thrive in any freely drained, cool, non-calcareous loam with the addition of some leaf-mould about the roots and an occasional top-dressing of the latter and a little old cow manure. Since the flowers are liable to be affected by late frosts, a westerly aspect should be selected, and partial shade is no drawback to successful culture. There is a double-flowered white form and a very lovely one often listed as *R. l. narcissiflorum* var. *plenum* which has large double flowers in a delicate shade of bluish lavender.

THE WHITE-BRACTED HOUTTUYNIA CORDATA.

SOME BORDER CARNATIONS AND CLOVES

During the past summer the writer tried out in his Yorkshire garden a number of well reputed varieties sent out by Mr. James Douglas and Messrs. Lowe and Gibson.

THE season did not prove to be one of the best as far as Border Carnations were concerned, but many of the following proved very reliable, and others may redeem their failures in a more favourable year.

APOLLO.—This variety, out of those that I tried, was perhaps least affected by the wet. It is a very strong grower with long, rigid stems, and the bright red markings are very clear and dainty on the pure white ground.

BEAUTY is a strong grower, and the flowers are of good size and form, but the colour, rose pink, is not as soft a shade as I should like.

BLUSH CLOVE.—A very fine variety, this has very rigid stems and a grand habit, also very powerfully scented. The colour is inclined to be "washy," and may be described as pale bluish.

BOOKHAM BELLE.—A good grower and free-flowering, but the blooms do not stand up quite as well as some of the other fancies. I am not enamoured with the colour—lavender grey and apricot on a yellow ground. The combination of tints gives it rather too much of a "jazz" effect.

CENTURION.—This is a most brilliantly coloured fancy, bright scarlet on a yellow ground. The habit is good and the flowers of splendid form.

CLARET CLOVE.—Very free-flowering and of strong habit, this gives large blooms of perfect

form, and there is a powerful fragrance. The colour is a deep wine crimson.

CORALLINA.—This is a most exquisite shade of rich coral, and it is very beautiful under artificial light. The plant has a vigorous habit, and the stems are long and strong. The blooms are not too full and open well in wet weather.

GLOWWORM.—Of a rather dwarf type, with bright scarlet flowers, this was not outstanding, but may do better as a two year old.

GONDOLIER.—I do not care for the colour of this, although it is distinct, being carmine-purple on yellow. Carmine, especially with a blend of purple in it, never makes a pleasing colour in flowers.

HERCULES.—This is the only variety in the kinds under review that gave a burst bloom. It is too large to open properly in our northern climate in an unfavourable season. The colour is a deep crimson-maroon.

KING OF CLOVES.—A very vigorous grower with a fine border habit, rich glowing wine crimson in colour, it is probably the best dark Clove yet raised at Edenside.

LOYALTY.—The season did not suit this variety, as the wet frequently spoiled the blooms just as they were about to open. The colour is pleasing—orange apricot—and in a dry summer it should be very fine

MARECHAL NIEL.—This is not as free as I should like it, and impatient of the wet. One or two of the first blooms were good, and reminiscent of the colour of the grand old Rose of the same name.

MARGARET KEEPE.—Here we have a beauty of fine habit and strong growth. The perfect blooms last a long time in good condition, and the stems are of great length and strength. The colour is a little deeper than Blush Clove, and, of the two, I much prefer it.

MRS. HAWKS BEE.—This daintily marked white-ground fancy, with light bars of rosy crimson at the tips of the petals, is not too strong a grower with me so far, but may improve when it settles down.

PRAIRIE BELLE is a very good border white and reliable in any kind of weather. It is a good grower and very free.

ROSALIND.—This is a very beautifully coloured fancy, salmon pink on a canary yellow ground. A good doer, and with flowers of fine form and substance, it is a variety that I can recommend.

SCARLET CLOVE.—I had blooms of this right down to the first frosts. It is of fine colouring, deeper in the young flowers than in the older blooms, but always striking. It is one of the strongest growers among the newer Cloves, and the stems are long and strong.

CLOVE-SCENTED CARNATION KING OF CLOVES.

THE VERY HANDSOME FANCY CARNATION JESSIE MURRAY

THE LADY COLWYN—This is a white-ground fancy with heavy, dark, on-maroon markings. Steerforth is a very good variety. **SILVER LILY**.—This was the best of the newer varieties I obtained from Edenside. It varies little in colour according to the weather, but the richest blooms are magnificent. It has a splendid habit and all the good qualities of a first-rate variety.

SUNSHINE. This is not very robust and is rather shy to flower. It may do better next year, but I think Mr. Douglas's new variety **Bookham Yellow** will supersede it.

WHITE CLOVE. This has a grand habit, and the flowers are of good form and very fragrant. I am looking for great things from this next year, as Mr. Douglas tells me that it is wonderful the second season.

So much for the Edenside productions. Now let us consider some of the best from Crawley Down.

BORDER CLOVE is probably the darkest of all the Cloves, and it is a very strong grower with a perfect border habit, besides possessing the full measure of perfume.

DAVID STOBART.—There is a warm tone in the colour of this fancy, and those who like a blend

of indiotrope and yellow will be pleased with it. It is a well formed flower with a broad, clear-cut petal.

DR. RAYMOND CRAWFORD. This is one of the best of the orange-buff selfs, very free-flowering, and more reliable than Elizabeth Shifner.

ELDORADO.—A very fine rich yellow of grand form and substance.

MARY MURRAY. I should have no hesitation in declaring this to be the finest yellow self, with Eldorado a good second. Mary Murray is a very strong grower, and the stems are long and strong. It does very well in the North.

J. SAVILLE.—This is variable in colour, but always interesting. Lavender and rose red are the predominating colours, and these are overlaid on a rich apricot ground.

JAMES GRIGGS is one of the nondescript fancies, a soft lavender grey with a band of bright rose. It is a flower of fine form and substance.

JESSIE MURRAY.—This is another very reliable variety, especially for Northern gardens. It is a white-ground fancy with distinct markings of lavender mauve, and possesses all the best qualities of an ideal Border Carnation.

KATHIE MOORE.—This is a most beautiful

colour blend, a yellow-ground fancy with heavy markings of rose pink. It has a grand habit and is excellent in every way.

LADY COLWYN is an attractive variety, apricot, edged and splashed with coral red. It is most distinct, and is a strong grower with a splendid non-splitting calyx.

LADY SHACKLETON.—Those who have admired Lieutenant Shackleton at the shows and have failed to grow it well will find Lady Shackleton much superior and of similar colouring.

MAISIE LOWE is another thoroughly reliable variety, a very daintily marked white-ground fancy with light pencillings of old rose. It is a splendid grower and the flowers are of excellent form.

MRS. EDMUND CHARRINGTON—the name almost implies it—must be regarded as one of the best of the white-ground fancies. It is distinct from Jessie Murray and makes a fine companion flower to this variety. The flowers are large and of fine form.

OAKFIELD CRIMSON has a delightful velvety finish about its rich deep crimson flowers, and it is a new variety that will certainly come to the fore when better known. **NORMAN LAMBERT**.

GARDEN DESIGN.—V

Borders in Separate Colours.

AS well as mixed borders the owners of fairly extensive gardens will probably like to have borders in separate colours. Blue borders in some secluded part of the grounds and amid a setting of green lawns and trees can appear delightfully cool in hot summer weather, and blue in its many shades is a colour of which nearly everyone is fond.

To a great extent the successful design of any garden or grounds is very largely dependent upon the balanced placing of the principal gardens or features, and after this, of the happy arrangement of the intervening spaces. To listen to a symphony or sonata consisting entirely of climaxes would be a nerve-racking experience and it would be equally trying to walk through gardens without

the quiet setting of lawns and walks, so placed as to give contrast and to connect and lead up to the principal features.

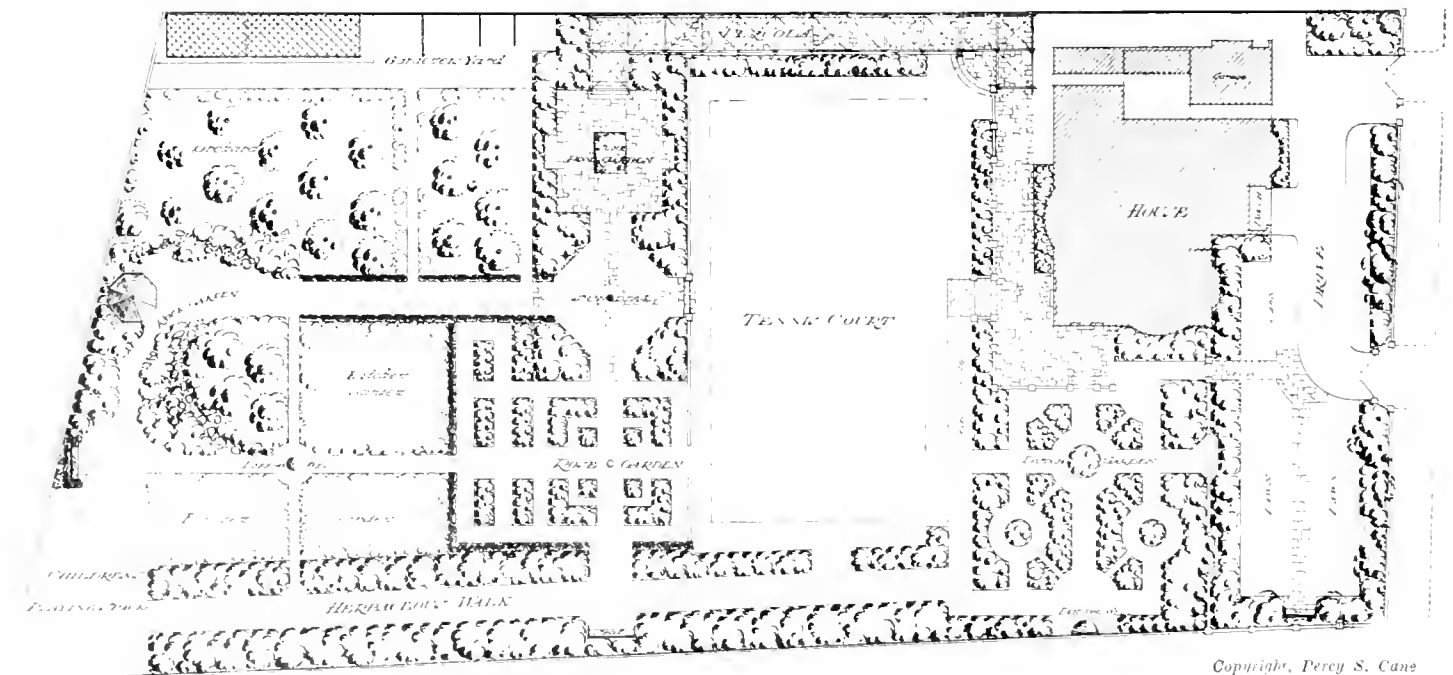

This happy disposition of planning is just as essential in the making of borders of separate colours as it is in the case of every other part of garden design. Blue never looks so well as when seen against a background of green or perhaps green and grey stone walling away from the formal part of the garden.

Borders of Delphiniums only, look extremely well, and there are varieties enough of these beautiful plants sufficiently different in their habit of growth and character to give endless scope in their arrangement. Like many other of the plant families there is an affinity in their range of colour

and height. These can be selected from the low-growing Blue Butterfly to the tall and stately masterpieces offered by firms which have specialised in the raising of these handsome plants.

Some shades of blue seem particularly effective against green. *Anchusa italica* gains immensely in effect if it can be grown in great isolated masses, and both *A. Dropmore* and *A. Opal* are worth growing in large beds by themselves.

Just as blue is for the cooler parts of the garden, so should a yellow or gold border be in as sunny a position as possible, so that even subdued sunlight may transform otherwise dull shadow into colours glowing with reflected brilliance and light. Flowers, trees or leaves seen on a dull day under leaden skies cannot be compared to the radiance that

DESIGN FOR A SEMI-URBAN GARDEN.

Copyright, Percy S. Cane

results from the sun flashing on dew-laden flowers and foliage; golds and yellows being particularly suitable for this purpose. A most effective border or garden could be arranged by using all the shades of yellow and gold, from the deep cream and lemon yellow *Anthemis* and *Gaillardias* to the deeper tones of *Coreopsis*, *Sunflowers* and *Day Lilies*, leading up to the purple and bronzy foliage of certain of the genus *Prunus*, *Paeonies* and other foliage plants of similar tone. Apart from the colour of their flowers, the leaves of many plants have a wonderful decorative value and Nature usually provides foliage for each plant that makes the best possible harmony of colour with the flowers.

Many plants, such as *Delphiniums*, the choicer *Lupins*, *Mimulus*, *Lavender*, *Gaillardias* and *Chrysanthemum maximum*, can be used as permanent residents, but care must be exercised in the use and placing of the coarser growing plants, such as *Verbascums*, *Anchusas*, *Hollyhocks* and *Rudbeckias*.

SOME OTHER FEATURES.

I should like in this article to add a few words on other features and parts of the garden. To an artist the interweaving of the various parts that go to make a successful whole, is an interesting task.

First, the contours of the ground must be carefully considered and so dealt with that full advantage is taken of every existing natural feature and the whole conception welded into a comprehensive treatment.

Next, the form of the planting will call for attention and in this connexion it must be emphasised that balance of form is, if possible, of more importance even than balance of colour.

To secure this the position of the larger masses of trees and shrubs must be carefully considered, so that in any glade or walk the masses on the one side, although these may be of different varieties, are, nevertheless, felt to be suitably balanced by those on the opposite side.

In wider and more extensive walks it will be necessary to fix the position of the tallest standard trees first, giving consideration both to their height and the colour of their flowers and foliage.

The pink, rose and red of the flowering Apples, Plums and Cherries may be employed almost anywhere with fine effect, but the introduction of such bright yellows as *Laburnum* should be used with discretion and in carefully selected places. In practice it is generally safe to make pinks and reds the predominating colour in one section, yellows, bronzes, etc., in another location and then to link them together in such a way that a right and happy transition is felt. This can be done by introducing some pale yellows among the lighter pinks and by planting bushes of intermediate or neutral colours at the junctions.

After the positions for the deciduous standard trees have been decided upon, the places of the larger conifers and other evergreens should be determined, again carefully studying the ultimate balance. After this is done, the lower and smaller planting may be undertaken. To do this successfully a comprehensive knowledge of the habit of growth and the colour and season of flowering of the various plants and shrubs is essential.

PAVED GARDENS.

Paving is largely used nowadays and for many good reasons. It is serviceable as a dry walk, beautiful for its varieties of tone and colour and can be made to form an essential part of the design of a garden. It should, however, be well and truly laid on a properly levelled surface.

One sees too frequently badly laid crazy paving in cases when other equally suitable materials might have been employed. Brick paths, especially in conjunction with brick houses and formed with warm red or plum-coloured bricks, can be very

effective and, if properly done, stone and tiles on edge can be introduced to form a pleasing variety in the texture of the path.

The planting of a paved garden calls for a distinctive treatment. Perhaps the most pleasing way to arrange this is to clothe the boundaries with evergreen and flowering plants in order to provide a suitable background, to fill in the back of the borders with herbaceous plants that are of medium height or fairly tall in their habit of growth, gradually reducing the height of the planting as it nears the front of the border. Although the planting may be largely herbaceous in character the result should be very much richer in colouring than in the case of the herbaceous border.

The peculiarities of growth and the need for pruning should be particularly studied, for many shrubs (such as the *Barberries* and *Cotoneasters*)

will be rendered ineffective or may even be ruined by being carelessly or excessively cut.

In the more natural planting of glades and walks, especially in those where great care has been exercised in the placing and selection of the various units, every plant, stone or tree should be so placed that it could not be removed without, to some extent, spoiling the whole design. This perfection in planting is very clearly evidenced in Japanese gardens, which are often a very high expression of the garden designer's art.

Finally, I should like to reiterate the need for a proper balance and adjustment both of form and colour. The creation of this balance is perhaps the highest expression of the art of the garden designer, and the exercise of this should gradually tend towards an increasingly high standard of achievement.

PERCY S. CANE.

FOLIAGE SHRUBS IN A WINTER GARDEN

IT is not until autumn gives way to winter that the full beauty of many evergreen shrubs and trees becomes really manifest. Nor is this merely a matter of comparative values or of contrast. In the absence of blossom, and with deciduous trees and shrubs devoid of foliage, evergreens, having the field

hue of its foliage, withdrawing the green and intensifying the yellow, so that by December every needle is gleaming like polished brass.

To some extent the same transformation takes place in other golden-leaved Conifers. The slow-growing *Lawson Cypress* called *Cupressus Lawsoniana* var. *lutea* now wears an unusual brilliance,

but more marked is the same change in the much more beautiful *C. macrocarpa aurea*, of which the feathery foliage, borne on chestnut red stems, has been regilded from base to tip. Of the golden *Junipers* and many another conifer no less might be written. Then there are those two beautiful forms of *Calluna vulgaris*, *aurea* and *cuprea*. These are of small account at any other season, and as flowering varieties they are exceedingly poor; but early winter brings to the one a golden yellow that is distinctly effective and to the other a warm coppery tint which is very lovely in any light, especially so when the foliage is wet or when it gives back the red glow of a frosty sunset.

As with gold so it is with blue, and I need not dilate upon the colder, bluer winter colour that comes to *Cedrus atlantica glauca*, to some of the *Pines*, *Spruces* and *Cypresses*. One or two of the dwarf, or slow-growing, *Thuyas* now powder their pale green of summer with the bloom of a ripe grape blended with plum red and, again, there are the *Junipers*. The common *Juniperus communis* here changes from its summer bluish green to a more intensely glaucous hue at the same time as the Scots Pine mentioned is putting on its winter colour, and a dwarf and quite prostrate form of this species found

growing wild on the Welsh mountains (not on limestone) promises to get even bluer than the tall, more erect type.

But of all the grey-leaved shrubs grown here none effects so thorough a transformation as *Convolvulus Cneorum*. Throughout the summer and autumn the foliage of this pretty thing is neither green nor grey, a feeble effort at being both. But now the leaves are so silvered with silky down that every vestige of green has completely vanished and the foliage gleams with the

THE TREE HEATH, *ERICA ARBOREA*, SO HANDSOME IN WINTER.

to themselves, might very well be expected to meet with a fuller appreciation than they enjoy at other seasons. But I refer here to the number of varieties which possess those peculiar and intrinsic merits which are never seen in such perfection as they are in winter.

Take that dwarf Scots Pine, *Pinus sylvestris aurea*, in all respects, save colour, a miniature of the type. This little tree will all summer have been a dingy yellowish green, but during the later days of autumn it begins to change the

of a few pieces of silver fresh from the mint.

In a lesser degree the same pleasant change occurs in *Tenerium fruticosum*, leaf and branch being markedly whiter than they were two months ago. One wishes that one might say the same of *Senecio Greyi* and *S. laxifolius*, but these, like a good many other downy-leaved, sun-loving subjects, wisely reserve their refurbishing until there is some hope of spring and drier weather. I have, however, been curious to know how that very remarkable shrub *S. rotundifolia* will behave in our winters. While its younger wood and the underparts of the large, broad, fleshy leaves are thickly coated with a dense ivory white felt, the upper surface is a strong, pure ivy green and highly glossed—the most striking contrast of the kind I have ever seen. As I do not even know where this stranger hails from, its future is a matter of speculation, but it has already stood 10° of frost without flinching.

There is a certain general resemblance between the foliage of *S. rotundifolia* and *Eleagnus macrophylla*. Though the leaves of the latter are smaller and of thinner texture, and the colour contrast alluded to is not nearly so strong, they are of much the same shape (broadly oval with a round base and sharply pointed). They have silvery underparts, a green upper surface and the same habit of waving the margins as if to display the white beneath. But, unlike the spongy felt of the *Senecio*, the silveriness of *E. macrophylla* is a hard metallic burnish. The young leaves in spring are completely coated with this curious aluminium sheen, but it is when the shrub has settled down to winter that the softer wood and undersides of the mature foliage are at their whitest. The North American *E. argentea* is perhaps the most silvery shrub known to our gardens, but it is deciduous. *E. pungens*, var. *aureo-variegata*, to turn once more to gold-leaved plants, is a shrub which in its full winter beauty even those who most dislike variegated plants cannot fail to admire. And, after all, there is a glow of warmth, very comforting in winter, about plants of this kind in a really deep yellow which none of those of paler hue, and much less the glaucous or white, can ever afford. Though we have grown several of these Oleasters for some ten odd years, none has ever yet borne a flower.

In shrubs, other than Conifers, with green foliage (and what is more cheerful on a winter's day than a fresh and kindly green?) I always think the most delightful are those which are "livening up" for their flowering period. These include various kinds of *Ericas*, notably the Tree Heaths, *EE. codonodes* and *Veitchii*, of which the foliage, so soft and plumose, is the most restful shade of moss green that one could desire. It is always beautiful, but never quite so fresh and charming as when the shrubs are putting out their countless little buds in preparation for the first hint of spring. *EE. arborea* and *alpina* come close to the above in colour, but the leafage is hardly so fine. The only trouble that one ever associates with these beautiful Heaths is the snow which clings so tenaciously to their foliage that they sink beneath the burden they were never built to bear, and break. *E. australis* is also liable to suffer in the same way, and the bluer green of its handsome foliage is also a more telling colour now that its flower-buds are beginning to shew than at any other season.

E. stricta, which, unlike the above, has only just ceased flowering, comes in colour of leaf somewhere between the Tree Heaths mentioned and *E. australis*. This forms a very striking object in the winter garden with its curiously fuzzy foliage, which makes such an attractive setting for the rusty red of the faded corollas

clustered at the tips of the rigid, upright growths. A distinctly livelier green has lately invested the masses of *E. carnea* which carpet the ground beneath some of our old Oaks, for it, too, will shortly break into colour. There is also something to be said for *E. scoparia* as a winter foliage shrub, the leafage being a pleasing green and the habit of growth extremely elegant. *Erica scoparia*, however, needs to be prevented from becoming lanky, overgrown bushes being thin and scraggy. For carpeting or associating with other lowly shrubs for winter effect the prostrate form of *E. scoparia* is well worth a place.

Two other shrubs which, in their unrestrained eagerness to reach forward to the spring, have

developed a sappier, more tender verdure, very tempting to the mischievous fingers of the frost, are *Genista fragrans* and *Coronilla glauca*. Though reputedly delicate, the former seldom takes much harm here, especially when grouped rather thickly on a very dry bank where the bushes nearly die of drought in summer. Indeed, it has withstood frosts which have seriously injured shrubs generally considered to be much hardier, and as much may be said of the *Coronilla*. Both of these appear to make full summer their time of rest (perhaps making a virtue of necessity as I have suggested), for from autumn to spring they may flower at any odd interval that the weather will allow.

A. T. J.

CORRESPONDENCE

A GARDEN NOTE BOOK.

I HAVE read with profit and interest the very indulgent review of my book (page 654), and the least I can do is to express regret for misspellings and for the improper use of capital initials in specific names. Personally, I detest seeing a page disfigured by redundant capital letters; my misuse of them arose from imperfect recollection of Article 26 of the International Rules for Botanical Nomenclature agreed to at Vienna in 1905. Therein it is laid down that "Specific names begin with a small letter, except those which are taken from names of persons (substantives or adjectives) or those which are old generic names." No mention is made of specific names taken from countries or places, which, according to this rule, should be written with a small initial. *Mea culpa!* But when your reviewer gently trounces me for error in the case of personal names in the genitive case, as *Rhododendron Fargesii*, I submit that there is classical precedent for the shorter form. In bestowing upon any plant a modern proper name as its specific designation, that name has first to be given a Latin termination, thus the surname "Farges" may with equal propriety be transformed into *Fargesus* or *Fargesius*, whereof the

genitive case would be respectively *Fargesii* or *Fargesii*. Even if the latter be the form chosen, it is quite in accordance with Latin orthography to write it *Fargesii*, which in my humble opinion is the preferable form and nearer the original *Farges*. I could support my contention by innumerable instances in classical Latin. I will only cite one as an illustration taken at random. Horace, *Sermonum* ii, 1, line 65, has

"Quid? cum est Lucilius ausus

Primus in hunc operis componere carmina morem," and in line 75 of the same poem, referring to the same person,

"Quidquid sum ego, quamvis

Infra Lucili censum ingeniumque."

It is surely more desirable to render scientific terminology as concise as possible than to make it more polysyllabic than is necessary.—HERBERT MAXWELL, *Monreith*.

THE USE OF POLYANTHUS.

I HAVE had it in my mind for some time to raise the question as to the use of the *Polyanthus* in gardening. I seem often to see this beautiful flower nowadays grouped boldly in woodland, and to be quite frank do not consider it suitable for the purpose; it is, I think, too sophisticated. I do

POLYANTHUSES IN WOODLAND AT ABBOTSWOOD, GLOUCESTERSHIRE.

not quite know why I feel thus about it. Colonies of Blue Primroses in a similar position seem natural and "at home," so do the charming coloured Cowslips, so that no question of principle seems to enter into the matter; still I do not like Polyanthus there, and I know that others share my prejudice, if prejudice it be. I think it must be that the florist has done a little too much for the Polyanthus to make it suitable for semi-wild gardening. Perhaps other readers will give us their ideas upon the subject. I ought to make it clear that I have no antipathy to the Polyanthus as a garden flower; indeed, it is one which I greatly admire.—N. H. P.

A FORGOTTEN PANSY?

I SHOULD like to know if any of your readers know of a very old Heart's-ease. It used to grow and seed year after year in an old garden at Kelso, New South Wales, over seventy years ago, where it was planted by the writer's grandfather, who, I think, brought the seed originally from Wiltshire. It was a deep purple in colour with yellow rays and very sweetly scented; in shape very like *Viola gracilis*. I am afraid it has become extinct, but should be pleased to hear if any of your readers know where it is to be found.—F. S. LEE.

"GODFATHERS."

IN a garden that I know very well two men had been deep-digging a patch of ground all afternoon, when they had very nearly got to the end one of them said to the other, "I say, Tom, we won't want any Godfathers, will we?" The meaning was that the speaker thought there would be ample soil put on one side to fill up the last trench. My gardener, who is a local man, tells me that a similar expression was a very favourite one of his old father, who, when he had nearly got to the end of his digging would say, "I'll be wanting some Godfathers," or "I'll have enough Godfathers." He (the father) always used the word in connexion with digging and the son (my gardener) has never heard it used in any other connexion. Another old inhabitant of the parish whom I asked about it knew the expression but did not think its use was limited to digging. Several young people, whom I have asked about it, have never heard it. It seems that this is one of the many quaint words that are gradually dying out. Is the word used in this way a local usage on a par with "Betty-go-to-bed-at-noon" (*Ornithogalum umbellatum*), and "rices" (older form, rises) for pea sticks; or is it a more general one? How came Godfathers to be used in this connexion at all?—JOSEPH JACOB.

[In "Shakespeare's Country," though the use of "godfathers" or "godfeythers" in the sense mentioned by Mr. Jacob is not unknown, the word is often used, in the singular, to denote a subsidiary or sustaining post. If a gate post, for example (or a pergola post, for that matter), is moved to another position and does not seem over strong at the ground line, another piece of timber is spiked or bolted to it, and this the countryman calls a "godfather." Similarly, when wire fences are being erected, the struts to prevent the posts giving to the tension are called "godfathers" and are commonly ordered under that name from the timber merchant. In this sense the application of the word seems obvious, and, as regards soil to "make up," probably the same idea suggested the use of the word.—ED.]

CLEMATISES ON THEIR OWN ROOTS.

MR. W. GATER, Sheffield, in your issue for December 8, page 640, will probably be able to obtain what he requires from Messrs. Pennell and Sons of Lincoln, as I saw this firm advertising Clematisses on their own roots recently

in *Country Life*. His experience is typical of that of hundreds of others, judging by the correspondence I have received on the subject since my article appeared in THE GARDEN.—E. MARKHAM, *Gravelly Mangr Gardens, East Grinstead.*

HYBRID BUDDLEIAS

ONE of the achievements brought to light in 1923, the new hybrids between *Buddleia variabilis* and *B. globosa*, seems to have been passed over with very little comment. It is passing strange that the cross should not have been attempted before, but stranger still, at least to a gardener who knows little of botanical research, is the attempt of the "mules" to arrange the globose clusters of the fragrant *globosa* in the panicle form of *variabilis*. It is noteworthy, too, that the blossoms which expand yellow or creamy, pass off violet. I, for one, shall be interested to watch the progress of these hybrids.—H. H.

A NEGLECTED PLANT.

CALAMINTHA grandiflora is a somewhat neglected plant at the present day, notwithstanding its hardy character and easy cultivation. It is a European plant introduced to this country from Italy. I have had experience with it in the lowest part of a garden, where the temperature was down at zero and perhaps below it occasionally in severe winters, and yet it was never injured in the least. I saw a patch of it, recently, a yard in diameter, at Cliveden, Shenfield, Essex. The flowers are large for this group of plants and of a pleasing rose purple colour. The stems are only 1 ft. in height, and stand nearly erect, but when a patch is allowed to get large they bend outwards at the base in such a way that the flowers are shown off to the best advantage. At present *C. alpina* seems the most popular member of the genus for the rockery, but the dark purple flowers are not half so conspicuous as those of *C. grandiflora*, which would be quite suitable for a large rockery.—J. F.

PRUNING LAVENDER.

WILL Mr. R. C. Jolliffe tell us why he recommends Lavender to be cut back hard in autumn? Why not cut early in April, so that the stumps may be quickly reclothed?—WILL TAYLER, *Godalming.*

A FINE FORM OF SAXIFRAGA COTYLEDON.

ALL who know *Saxifraga Cotyledon* var. *platyphylla* will, I think, agree that it is far the best of the various forms of *Saxifraga Cotyledon* in cultivation. Grown in pots as a decorative plant for the alpine house it has few equals; it

is also a splendid plant for house decoration. When well grown its graceful inflorescences of white flowers easily attain 5 ft. in length and 2 ft.

THE NEW HYBRID BUDDLEIA GOLDEN GLOW.

through at the broadest point, arching over in a most elegant manner, remaining in flower and retaining its snowy whiteness for an exceptionally long time, thus adding greatly to its usefulness.

The cultivation of *S. Cotyledon* var. *platyphylla* presents no difficulties, and a stock is easily maintained by offsets taken annually and dibbled into shallow, well drained pans of sandy soil and placed in a cold frame. This may be done really at any time when offsets are obtainable, but presuming it is done during autumn, the plants should be ready for potting into small pots the following April or May and be returned to the frame until the end of July, when they will require a move into a size larger pot. Except for watering and pulling out the offsets, the plants need no further attention until late spring of the following year, when they should have their final potting into 5 in. pots, using a compost of loam, leaf-mould, old mortar rubble and grit. This time pot more firmly. At this later stage the plants are better accommodated in the alpine house, where they should all flower the following May and June. Although this is a slow process, it is not advisable to push this class of plant. Care must be exercised not to over-water, and avoid wetting the rosettes as far as possible, or the plants will not possess the silvery hue so desirable.—J. T. H., *Dupplin.*

[J. T. H. omits to stress the very real beauty of the foliage of this stately Saxifrage; the rosettes are almost as beautiful as the giant flower spikes.—ED.]

CABBAGES AND CATERPILLARS

THE above do not form a pleasant combination, and one of the most difficult problems of the gardener relates to the choice of methods to prevent its possibility. Two butterflies and one moth deluge us with many of the eggs which hatch into these troublesome intruders, and since these eggs are very small and difficult to find among leaves which fit one into another like those of the Cabbage, and as the caterpillars also hide themselves among brittle leaf-stalks so that it is difficult to dislodge them without spoiling the vegetable, it is better to deal with the perfect forms of the insect.

The butterflies which give us so much trouble are both of the genus *Pieris*, and are known among us familiarly as the Garden Whites, Large and Small respectively. They fly by day, and love warmth and sunshine. They are white and mostly have black tips to the upper sides of their two front wings, also a few black spots. Under this description may be comprehended two other butterflies, the Green-veined White and also the Bath (or Chequered) White, the under-surfaces of the hinder wings of which are beautifully mottled with green and white, but which is sufficiently rare to make it a valued find for collectors. The underside of the Green-veined White gives it its common name. While it is supposed to lay its eggs upon such plants as Mustard and Water Cress, its caterpillars are not too particular as to their food plant. Ignoring, then, its claims for toleration and recognising the rarity of the Bath White and the unlikelihood that it should favour any given spot with its distinguished presence, the horticulturist may perhaps be pardoned if he issue a decree of banishment against the whole tribe of white-winged butterflies. How to enforce the decree is an awkward question.

In April and May (also for the second brood in July and August) the eggs are deposited, and after ten days or a fortnight, according to the weather, hatch into little pale green caterpillars and commence their career of destruction. The eggs are spindle-shaped, standing on an end, and are ribbed, with fine transverse markings. They are of a greenish or pale yellow tint. The caterpillars of the larger species sometimes reach 2 ins. in length, taking a month or more for their growth. Their backs are then dull green, inclined to grey or blue, and marked with black; lines of yellow run along the back and sides, but the younger caterpillars vary in tint, according to their age. The caterpillar of the Small White is at first yellow, but later becomes green, keeping a yellow line along the back and spots of that colour along each side. The chrysalids of the Garden Whites have the angular shape which is so characteristic of this stage of the butterfly, and are of a greenish or greyish hue tinged sometimes with red and marked with black dots, larger in the larger species.

The question of how to guard the Cabbage from these insidious foes is most perplexing. As the vegetables are used for food, the risk would be too great were any poison to be employed as a deterrent spray, but there are proprietary preparations which profess to be safe and useful. Powdered Pyrethrum may be applied, but it is uncertain if the result be worth the expense. The best hope is in means that perhaps may appear slow and unpromising. A determined effort should be made to catch and deal with every Garden White that may intrude, for which purpose a small light butterfly net should be kept accessible. Walls and corners likely to shelter chrysalids

should be inspected regularly, and every Cabbage showing signs of attack by caterpillars should be promptly destroyed. Choice must be made

they shrink and change into pupæ of the usual brown colour. If the earth between the Cabbages be turned over to the depth of but a few inches many of these pupæ will probably be dealt with by the birds, and others killed by the weather. Poultry may with advantage be turned

CABBAGE PESTS.

Figs. 1, 2 and 3.—The Small White Butterfly, *Pieris rapæ*, with caterpillar and chrysalis.
4, 5 and 6.—Caterpillar, pupa and perfect insect of the Cabbage Moth, *Mamestra brassicæ*.

between the cheerful beauty of the fluttering butterfly and the cleanliness of undisturbed cabbage life. Of course, the term Cabbage here includes the tribe of Kale, Cauliflowers, etc.

The caterpillars of the Garden Whites, like those of many other species, are attacked by small four-winged flies called Ichneumonids, which pierce their skins with a sharp ovipositor and deposit several eggs in the body of their victim. These hatch in due course. The resulting maggots feed upon the tissues of their living host, avoiding vital organs, and finally build their cocoons and hatch. The caterpillar is doomed, and should the body of one be found infested with the small cocoons of its enemy, it should be put aside for them to hatch in safety, for undoubtedly the little flies are friends of the gardener.

The caterpillars of the cabbage moth are, if anything, more objectionable than those of the butterflies. They have a liking for the inside of the Cabbage, and leave it in a peculiarly insanitary condition, difficult for any cook to deal with. These caterpillars are of a tint inclined to green or brown which varies both individually and with age. The perfect insect may be looked for from early in May to September and later, is of a muddy tint of brown, and flies mostly in the evening. Its wings have a spread of about 1½ ins., and it has a habit of fluttering in windows and round lights which brings it frequently into notice. In the daytime it remains still in a quiet corner, falling to the ground if touched and running hastily into cover, though in bright sunshine it may be too dazed to move. It may be taken with a mixture of treacle and spirit painted, before dusk, as a stripe on a tree, post, wall, etc., near its haunts and examined after dark with a lantern or electric torch, when the moths may be taken with a net.

When full grown the caterpillars descend and make a burrow just below the surface, where

on to the freshly dug ground. Afterwards naphthalene may be employed, or lime carefully raked in will be found useful. After all, there is something in the careless remark of one young gardener, "I leave the caterpillars to the birds," though to most people supplementary means appear advisable.

M. L. B.

THE PHŒNICIAN MULLEIN

SOME of the taller Mulleins are too big for the small garden or narrow border, but this cannot be said of the Phœnician one, *Verbascum phœniceum*. While such species as *V. olympicum* may tower up 6 ft., 7 ft. or even 10 ft. high, the Phœnician Mullein contents itself with a height of 18 ins. or 2 ft. at the most, so that it may be grown in places where the others would be out of place. It is, moreover, a true perennial, coming up year after year, increasing in size annually, and throwing up more and more of its spikes of pretty flowers. In olden times its flowers seem all to have been purple, but nowadays we have varied colours, owing to hybridisation, according to certain writers, but only seedling variations in the opinion of others. If the reader buys a packet of *V. phœniceum*, either as "mixed" or as *V. p.* "hybrids," he or she is almost sure to have a nice set of varieties, with flowers of different shades of purple, salmon, orange and almost pink, nearly every one very beautiful. The flowers begin to open from the base of the spike, which gradually lengthens. They are of good size and, when open, are attractive in the border. The plants flourish well in light soil in sun or half-shade, and continue in bloom for months in summer. Seeds may be sown from April in shallow drills in the open or in pots or boxes under glass. Thin out the seedlings well and they will bloom the following year.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Seed Catalogues.—Once more the time has arrived for making out the seed order, and it is always advisable to dispatch it to the seedsman as early as possible, thereby preventing delay and disappointment. A rough plan of the kitchen garden should be prepared and then a selection of seeds made, always relying upon kinds that have proved their worth. However, I always like to try a few novelties each year. Among the first to receive attention will be Peas. These can never be produced too early, and last season I found Pioneer and Langley Gem (both dwarf varieties) did remarkably well, as did Cauliflower Magnum Bonum.

General Work.—Much can be done at this season to prevent a rush of work later on, and every advantage should be taken of wet days. Labels can be prepared and painted, pea sticks overhauled and new ones cut, stakes of various sizes looked out, seed and cutting boxes prepared and new ones made. All garden refuse should be collected and, where possible, buried in a trench, while that of a woody nature should be burnt. Garden walks may be regravelled and rolled from time to time to get a hard smooth surface. Continue to pay attention to Cauliflowers in frames, remove all dead leaves, and grow the plants as hard as possible by admitting air on all favourable occasions.

Early Peas.—A sowing of a dwarf variety may be made in pots, but it will be necessary to bring them along slowly, for coddling will mean failure. Pots 3½ ins. to 4 ins. in diameter will suffice, and they should be well provided with drainage and nearly filled with a mixture of good loam with a sprinkling of leaf-mould and sand. Sow the seeds thinly and eventually thin the seedlings to four or five in each pot. Place them in a cool house or frame and watch for mice, for these are often destructive.

Vegetables Under Glass.

Tomatoes.—In many gardens these cannot be produced too early, and seeds may now be sown from which ripe fruits may be expected about next May. A good way at this season is to sow three or four seeds in a 3 in. pot containing a mixture of loam, leaf-mould and sand. Place the pots in a warm house where the average temperature is about 60° and do not overwater the soil. When the young plants are well through the compost reduce the seedlings to one, leaving the strongest. Keep the plants near the root glass in order to promote a sturdy growth. Princess of Wales and Satisfaction are both useful kinds.

Fruits Under Glass.

Melons.—Early Melons may be fruited in pots 12 ins. or 12 ins. in diameter, and, where heated pits or small houses are available, there is no reason why a small sowing should not now be made. Sow the seeds singly in small pots, and a little bottom-heat will soon cause the seeds to germinate. In many houses and pits it is possible to introduce fermenting material, and when the rank steam has escaped, such a bed will be found very useful for raising these and other seeds. Water the soil sparingly and keep the plants in a light position. A temperature of 60° to 65° will be necessary.

Late Grapes.—It is not advisable to allow fruit to remain on the rods after this date, so the remaining bunches should be cut with as much stem as possible and all diseased berries be removed. The stems should then be placed in bottles containing water. Very few possess a fruit-room suitable for storing Grapes, but an ordinary room will suffice if the temperature does not fall below 50° Fahr. Prune and cleanse the rods and admit plenty of air.

The Hardy Fruit Garden.

Strawberries.—Established beds will be benefited by a mulching of manure. New plantations that were formed last autumn will not require any manurial assistance at present.

Raspberries may also be mulched and any suckers pulled up. The same remark applies to Loganberries.

Red and White Currants.—The pruning of these may be taken in hand as an opportunity occurs. The leading shoots should be cut back to about 6 ins., weak growths be removed and the remaining shoots reduced to three buds. Prune in such a way as to enable plenty of light and air to reach the centre of the bushes. Black Currants are

treated differently. Thin out the old wood and leave this season's growths their full length.

Gooseberries.—Unless these are fairly well thinned, the gathering of the fruit is very difficult and, moreover, it is often inferior in quality. The centre of the bushes should not be overcrowded, and any shoots near the soil may be cut off. When this is done the remainder of the shoots should be tipped. A sharp look-out should be kept for finches, which occasionally destroy a large number of fruit-buds.

The Flower Garden.

→ **Schizostylis coccinea.**—The Kalfir Lily with its scarlet flowers has been making a brave show during October and early November, and it is a plant that should be noted and grown in every garden. It will succeed in an ordinary border, and should be planted when the bulbs are more or less dormant.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chesham, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Asparagus.—Those who intend to make new plantations next spring should have the ground prepared now. Asparagus enjoys a light, rich, deeply-cultivated soil. Heavy soils can be lightened by the addition of such materials as sand, road scrapings (free from tar), leaf-mould or mould resulting from decayed vegetable refuse from the kitchen garden.

Onions.—Go over the stock occasionally and remove any decaying bulbs. Retain the best-ripened bulbs for latest supplies irrespective of size, which is no guide.

→ **General Work.**—While Celery, Leeks, Parsnips, Salsify and Jerusalem Artichokes are best lifted as required, a week or ten days' supply should either be lifted ahead of requirements or a keen look-out should be kept for frost, and if a sharp spell threatens, supplies should either be lifted or a portion of these crops should receive frost-proof protection. Complete the work of trenching or digging vacant ground as soon as possible, but never bury frozen soil.

Vegetables Under Glass.

Asparagus may be forced in a pit with a bed of leaves to supply slight bottom-heat and prevent too rapid evaporation. This forms the ideal conditions with a top temperature of 50° to 55°. The plants may either be set in an 8 in. layer of soil or several placed in pots 10 ins. to 12 ins. in diameter. The pots should be plunged in the fermenting material. Asparagus plants suffer quickly when out of the ground.

Tomatoes.—As soon as young plants have produced the first pair of true leaves they should be potted off singly. Use "thumbs" or at most 2½ in. pots, and employ a rather sandy soil. Place the plant near the side of the pot instead of in the centre as a preventive against damping off.

Kidney Beans.—A sowing may now be made in a temperature of from 55° to 60°. Sow in pots of from 9 ins. to 12 ins. in diameter, and place three or four seeds in a pot. Select a dwarf early variety, such as Ne Plus Ultra.

Mushrooms.—Prepare fermenting materials for making up a fresh bed or beds. Three parts of stable manure to one of fresh leaves forms a much better heating medium than pure stable manure, this mixture being less liable to "fire." Should the materials prove rather dry, sprinkle a little water on them as the work of mixing proceeds. Turn the materials twice before making up the bed.

Seakale.—Introduce another batch of roots and place under the staging, or place an inverted pot on the top of each pot having its complement of roots.

Fruits Under Glass.

The Early Vinery.—By the end of the week the buds should show signs of swelling, so the night temperature should be raised to 55°. Damp the floors morning and evening and spray the rods with tepid water when closing the ventilators on bright days.

Strawberries.—Move half of the stock from the cold frame to a suitable low span-roofed house, failing which either to the early peach house or early vinery, a night temperature of 50° being suitable for the first fortnight. Before moving, wash the pots, remove any decayed leaves and

slightly stir the surface soil with a pointed stick. If placed in a peach-house or vinery, stand on a shelf near the glass. Keep the plants rather on the dry side until growth becomes active, but the soil should not be allowed to become quite dry.

The Late Vinery.—The house should now be got ready for starting a few weeks hence. Wash down glass and woodwork, lime-wash walls, paint rods with Gishurst's Compound, remove a few inches of soil from surface of the border and replace with fresh loam plus some bone-meal or bonedour. This completed, water the border.

The Orchard-House.—Stone fruits in pots should not be left outside after October, but Apples and Pears—if the pots are protected from frost—respond more readily to the protection afforded by a glass structure after having been exposed to low temperatures for a time. The sooner those outside are now placed under glass the better. See that the pots are clean before removal. If any of the pots have to be stood on soil, a couple of bricks set a little apart should be placed under each pot to prevent the roots from pushing into the soil. Be sparing with water here, more especially with stone fruits until they begin to make growth. Do not apply fire-heat except to exclude frost, 40° being a sufficient minimum temperature. Ventilate freely, leaving some air on whenever the external temperature is above freezing point.

The Flower Garden.

Lenten Roses.—*Helleborus orientalis*, of which there are many beautiful varieties, will soon be opening its flowers, and beds of this should be protected from the weather with sashes. Single plants may have the protection of a hand-light or of a sheet of glass.

Bedding Plants in frames should be carefully watched, as damping often works havoc among them if neglected. Give abundance of air on all favourable occasions, stir the surface soil from time to time, and regularly remove all decaying foliage.

CHARLES COMFORT
(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Composts.—If not already done, a quantity of loam, leaf-soil and sand should be placed under cover. Although such material is best left outside as long as possible, a certain quantity, according to requirements, should be kept under cover to ensure it being in suitable condition for potting and seed sowing. Wood-ashes are very valuable for mixing with potting composts, but it should be stored in a dry place, for if allowed to become wet it is of no value. Although gardeners are generally fully aware of the value of lime in the garden, it is surprising how seldom they think of mixing it with potting soils. Most potting soils are almost sure to benefit by an application of lime, as they are usually cut from old meadow lands that all too often have been neglected as regards liming.

Hydrangeas that are required in flower early should now be introduced to a warm greenhouse with a temperature of 50° to 55°. For this purpose plants with strong prominent flower-buds should be selected. They should be carefully watered until they are well started into growth, after which the plants enjoy plentiful supplies of water at the root. Hydrangeas are very useful for flowering during the autumn. Where required for this purpose it is necessary to propagate young stock early in the year. In carrying out this work some stock plants should now be placed in a warm greenhouse. When they have made growth some 4 ins. in length the strongest should be secured as cuttings. These root readily in a close case, and should be grown steadily on during the summer, their final shift being into 6 in. pots, in which they may be allowed to flower.

Crassula lactea, which usually flowers during December, is deserving of more general cultivation, as it is very useful in the greenhouse at this time. *C. lactea* is a succulent plant and is not generally regarded as requiring high cultivation. However, this is a mistake, as it responds readily to generous treatment. This plant should be propagated each spring by means of cuttings, and it is best to use quite large pieces several inches in length, placing four or five pieces in a 48-sized pot. The cutting pots may then be stood on a shelf or bench in an ordinary greenhouse. When the cuttings are well rooted they should have a shift into 6 in. pots, in which they may be allowed to flower.

Nerines that have finished flowering should not on any account be neglected, as their future flowering depends on good cultivation during this, their growing period. They should be kept well up to the light in a cool, airy greenhouse. Well established plants will benefit by frequent applications of diluted liquid manure and soot-water.

Bomareas.—There are several species of *Bomarea* which are deserving of more general cultivation in the conservatory or greenhouse. Their alstroemeria-like flowers are very beautiful. The *Bomareas* are all climbers, and the beautiful *B. patocensis* with rich crimson flowers makes shoots some 15ft. to 20ft. in length. The umbels of flowers develop at the ends of the shoots, which should be cut out to make room for others when the flowers fade. *B. Carderi* is a very beautiful species with rose-coloured flowers, spotted purplish brown. Other desirable species are *B. B. Caldasiana*, *edulis*, *frondea* and *oblongata*. Although they can be grown in pots, they are seen at their best when planted out in a well drained bed in the greenhouse. These plants are best raised from seed, although they can be increased by careful division of the underground stem if a few roots are secured with each portion. They thrive in a mixture of good loam, leaf-soil and sand.

Mackaya bella.—This plant should be kept on the dry side during the winter months. The

inflorescences are now showing at the ends of the shoots and from now onwards any young lateral shoots that appear should be rubbed out, for if allowed to develop the flower-buds will drop off.

Tuberoses may be had in flower over a long period by growing them in successional batches. These plants are very useful for the conservatory. Plants that are well rooted and growing freely will enjoy frequent applications of diluted liquid manure and soot-water. At this time they require a temperature of 55° to 60°, but as the season advances they may be grown under cooler conditions. Before potting the dry tubers all dead roots should be removed and the side shoots rubbed out. The tubers may be potted single in 48-sized pots or several placed in a 6in. pot. After potting they should be given very little water until they have made a quantity of roots and started to grow.

Cantua buxifolia (syn. *dependens*).—This beautiful climber is now seldom seen in gardens. It is easily propagated by means of cuttings if placed under a bell-glass in a cool house. *C. buxifolia* is best planted out in a well drained bed in a cool greenhouse, training the shoots up under the roof glass. The plant is somewhat subject to attacks by red spider during the summer, but this may be prevented by frequent syringing.

Royal Botanic Gardens, Kew. J. COULTS.

EFFECTIVE COMBINATIONS OF HARDY FLOWERS

HARDY perennials have had a long run in mixed and massed borders, and their popularity in this direction is not likely to wane. It has, however, for a good number of years been widely declared that herbaceous plants must and would take the place of ordinary summer bedding, and while I am as ardent an enthusiast as anyone for hardy perennials, I am not quite sure that this particular claim on their behalf has yet been fulfilled to the extent anticipated by those who have urged it. It has to be acknowledged that comparatively few herbaceous plants are capable of maintaining an unbroken display of colour for a period comparable with the long season of a bed of Paul Crampel Geranium, or Zonal Pelargonium if you will have it thus, and it is useless to ignore the fact that there are situations and environments which render such consistency and brilliant effect as may be obtained from beds of Paul Crampel not only appropriate but essential. On the other hand, perhaps now more than ever there is desire and need for reducing labour to a minimum, and for dispensing so far as possible with fire-heat for preservation of tender plants during winter, so that any satisfactory scheme for utilising hardy perennials for more or less formal bedding arrangements would be welcomed in many quarters, and would tend to give yet another strong fillip to their grand march of progress.

My theme is that, while there are but few herbaceous plants which, alone, can challenge a bed of Geraniums to a contest of continuity, there are any number which by judicious combination may be made to keep even an isolated bed upon a lawn or formal beds on a terrace delightfully effective from the very beginning to the very end of the season. We may have combinations of plants of different character following each other in quick succession in such a manner that their bed is constantly attractive although frequently changing. In other cases we may have two or more kinds of plants flowering simultaneously, each helping to accentuate the beauty of the other.

Edge a large bed with a good *Aubrietia*. Plant *Hepaticas* thinly over the whole area of the bed,

interspersed with *St. Brigid Anemone*, and at intervals of 2ft. put in a stout crown of the double *Gypsophila*. By the time the *Anemones* are fading the airy panicles of *Gypsophila* will screen their foliage and protect their roots from scorching sun. By trimming over the *Aubrietia* as soon as the first flowers fade new growth and a continuation of bloom will be induced, and the entire bed will be strikingly effective from the bursting of the *Hepaticas* to the filmy cloud of *Gypsophila* in autumn. For another combination carpet a bed with *Saponaria ocymoides*. Plant roots of *Anthericum Liliago* reins. apart, and between these the brilliant autumn-flowering *Schizostylis coccinea*. The *Saponaria* will bloom from spring to midsummer, the glistening *Anthericum* showing to grand advantage above, while if the dead flowers are removed from the *Saponaria* it will make fresh green foliage under the dazzling scarlet of the *Schizostylis*.

Potentilla Gibson's Scarlet is one of the most consistent bloomers among hardy plants. Planted thinly over a bed with *Fritillarias* in between, and an edging of the golden *Alyssum saxatile* the combination will run even Geraniums off the course for brilliance and length of season.

A comparatively recent introduction and not yet so widely grown as it deserves to be, is *Pentstemon isophyllus*. It is of neat, shrubby habit, with glaucous foliage and coral scarlet blossoms, having to casual glance the appearance of *Pentstemon barbatus* flowers but set more closely on shorter, stiffer stems. From June right on to late autumn the plants make a brave show, and it is quite easy to precede their earliest blossoms by the disposal of bulbous *Iris*es between the plants and by using the early-flowering *Pentstemon heterophyllus* for the outer rows. The latter was in bloom with me last season before May was out, and continued to produce its steely blue flowers until well into autumn.

Iberis semperflorens makes a grand setting for the intensely brilliant spikes of *Lobelia fulgens* or one of its select varieties, and in the same bed an earlier display may be secured by planting *Veronica gentianoides* alternately with the *Lobelia*.

Æthionema Warley Rose is a wonderfully free-flowering dwarf plant, and the golden yellow

Linums, both *arborescens* and *flavum*, are of excellent character, as they will spread out to make a good even mass of foliage and bloom, while still allowing space for other spiky flowers to run up between them, either for simultaneous companionship or successional display. As early as April last I had a glorious bed of *Cheiranthus mutabilis* hybrids producing a sheet of uncommon art-shades of colour ranging from delicate mauve to deep claret. By periodically removing faded flower-spikes the same plants were kept incessantly in bloom until even the *Michaelmas Daisies* had given up. With clumps of *Liatris spicata* at stated intervals over the bed and, previously, *Anthericum*, a feature of outstanding charm was provided all the season through, and each of the three kinds benefited immensely by association.

There are wellnigh limitless possibilities in this method of arranging suitable companions. The examples I have quoted may not appeal to all, may not, in fact, be of service in every situation; the purpose of this article is not to dictate, but merely to suggest, and by instancing a few of the combinations I have tested during the past two or three years to induce others to plan and try schemes of their own. This much my efforts have shown me to be desirable—some plant of dwarf but loose habit of growth and free-flowering character should be planted not too thickly over the entire bed, and the plants interspersed should be of slender but erect growth without too much basal foliage. A dwarf plant that makes a veritable mat of foliage on the actual surface of the soil may prove an unhealthy companion for a plant with succulent stems, and at the same time a taller plant that makes a great mass of broad foliage may cause discomfort and distress for the carpeting plant beneath. Even in herbaceous borders there are kinds that may with advantage be similarly associated.

Florists' *Pentstemons* closely massed are always apt to damage each other by brushing in the wind, but planted widely enough apart to admit of *Viola cornuta* or some other low-growing plant with either blue or white flowers being interspersed, every individual spike of *Pentstemon* shows its whole charms to full effect.

The *Echinops* are fine, but a clump of several plants in a border makes rather a dull patch when viewed from a distance. Intermingled with the golden heads of *Centaurea macrocephala* the transformation is wonderful. Even the glorious blue of *Anchusa Dropmore Variety* is more glorious still if a plant or two of *Oenothera biennis* pushes its clear yellow blossoms between the candelabra of *Anchusa* flowers. A. J. MACSELF.

OBITUARY

W. H. L. LAXTON.

We regret to have to announce the death, in his fifty-eighth year, of Mr. W. H. L. Laxton of Laxton Brothers, the well known nursery firm of Bedford. Mr. Laxton, who passed away on the 14th inst., was a very well known, popular and highly respected member of the trade, and had for thirty-five years interested himself very largely in the raising of the new Peas, hardy fruits, etc., for which the firm is so widely famed.

Educated at Bedford Modern School, he afterwards proceeded to Germany and studied the practice of horticulture with Messrs. Haag and Schmitt; subsequently he spent a period with Messrs. Jackman and Sons of Woking before becoming a member of the firm of Laxton Brothers.

SEEDS—

good or bad—may look the same, but the difference between them is all the difference between your Garden being a pronounced success and a partial failure.

When you buy TOOGOOD'S GUARANTEED GARDEN SEEDS from the beneath Guide, the element of doubt is removed so far as is possible to human care and skill.

EVERY Packet MUST GROW FOR YOU and please you or you will get it REPLACED FREELY. You are the sole judge. We shall not be there to influence you.

TOOGOOD'S FREE GUIDE.

Our "Guide to Guaranteed Garden Seeds" is a beautifully illustrated book of 160 large pages—the safest guide to success in your Garden, and of real value to everyone who sows Seeds either for pleasure or profit. It is absolutely free. Write for it to-day, addressing us personally:

WAKELEY BROS. & CO., Ltd., 75a, BANKSIDE, LONDON, S.E.1.

NEW SPRAYING MACHINES LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete without a Sprayer, in fact a Sprayer is absolutely essential to obtain best results.

During the War we supplied a considerable number of our well known Four Oaks Knapsack Sprayers—Rubber Diaphragm type—to the Government, and we have just re-purchased a small quantity back again, which have never been used. They are

made of copper but painted Service grey colour. They have various special additions to the ordinary machines, and the price to-day would be £5 each. We guarantee them to be in perfect working order as new. We will send one machine carefully packed, carriage paid, on receipt of 50/-, but cash must accompany all orders. We would supply 2 machines for 90/-, carriage paid.

Please mention this Paper when ordering.
